# MEMORY ORGANIZATION

# MEMORY ORGANIZATION

Each process (a running program) has a chunk of memory at its disposal.

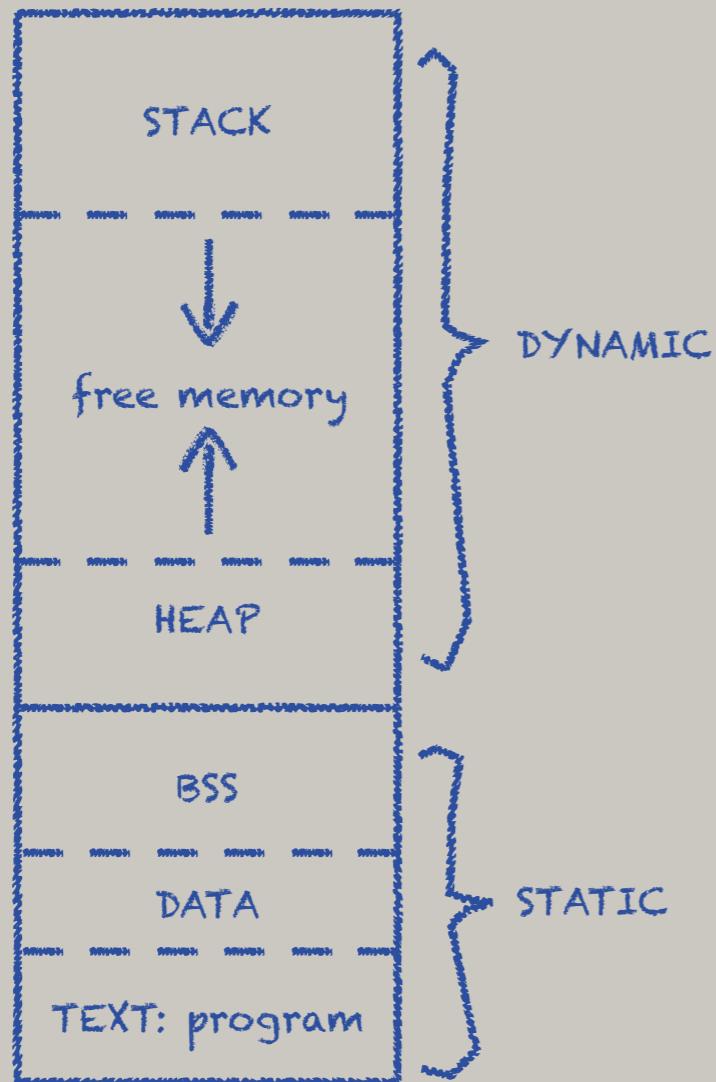

This memory is divided into "static" memory (allocated/structured before execution begins) and "dynamic" memory (allocated while the program executes).

# MEMORY ORGANIZATION

The static segment is divided into a TEXT segment (holding the machine language instructions of the program), a DATA segment (for initialized variables), and a BSS segment (for uninitialized but implicitly zero-assigned values).

# MEMORY ORGANIZATION

The STACK holds invocation records (also called stack frames).

An invocation record is created whenever a function is called. It has space for the function's parameters, local variables, any return value, as well as bookkeeping information related to the call itself (e.g. where to return to).

ACTIVITY

*Discussion*

INSPECT THIS PROGRAM, AND DESCRIBE AS BEST YOU CAN WHAT THIS PROGRAM WILL DO WHEN IT RUNS.

- It prints "x has value y" for 9 times where the value y are numbers 0-9 in order.
- It loops 10 times and prints the value of x to the terminal
- will print 10 times with " x has value \_\_"
- It will print "x has value \_" with values 0-9, each on a separate line, then it will exit.

When the program runs, it will print 10 lines.

x has value 0

x has value 1

x has value 2

x has value 3

x has value 4

x has value 5

x has value 6

x has value 7

x has value 8

x has value 9

# WHERE IN MEMORY WILL SPACE FOR THE VARIABLE X BE ALLOCATED?

- it will be stored in the stack
- The variable x is stored on the heap.
- `int x =0;` is the space allocated
- 'x' is located on the stack, the main's invocation record due to it being a local variable in main.

TRANSFORM THIS PROGRAM SO THAT THE VALUE BEING PRINTED IS STORED ON THE HEAP RATHER THAN ON THE STACK.

```
#include <stdio.h>
#include <stdlib.h>

int main() {
    int *x = new int();
    x* = 0;
    while (x < 10) {
        printf("x has value %d\n",x);
        x = x + 1;
    }
    exit(EXIT_SUCCESS);
}
```

```
#include <stdio.h>
#include <stdlib.h>

int x = 0;

int main() {
    while (x < 10) {
        printf("x has value %d\n",x);
        x = x + 1;
    }
    exit(EXIT_SUCCESS);
}
```

```
#include <stdio.h>
#include <stdlib.h>

int main() {
    int *x = (int *)calloc(0);

    while (x < 10) {
        printf("x has value %d\n",x);
        x = x + 1;
    }
    Free(x)
    exit(EXIT_SUCCESS);
}
```

TRANSFORM THIS PROGRAM SO THAT THE VALUE BEING PRINTED IS STORED ON THE HEAP RATHER THAN ON THE STACK.

```
#include <stdio.h>
#include <stdlib.h>

int main() {
    int *x = malloc(sizeof(8));
    x[0] = 0;
    while (x[0] < 10) {
        printf("x has value %d\n",
x[0]);
        x[0] = x[0] + 1;
    }
    exit(EXIT_SUCCESS);

    free(x);
}
```

```
#include <stdio.h>
#include <stdlib.h>

int main() {
    int *x;
    x = (int*)malloc(sizeof(int));
    while (*x < 10) {
        printf("x has value %d\n", *x);
        *x = *x + 1;
    }
    exit(EXIT_SUCCESS);
}
```

```
#include <stdio.h>
#include <stdlib.h>

int main() {
    int *x = malloc(sizeof(int),0);
    while (x < 10) {
        printf("x has value %d\n",x);
        x = x + 1;
    }
    free(*x);
    exit(EXIT_SUCCESS);
}
```

FINALLY, DO YOUR BEST TO FIX ANY COMPILATION ISSUES.

ONCE YOU HAVE ACHIEVED A CLEAN COMPILATION (OR YOU THROW IN THE TOWEL) GIVE THE CODE YOU ARRIVED AT BELOW:

```
#include <stdio.h>
#include <stdlib.h>
```

```
int main(void) {
```

```
    int* ptr = (int*) malloc(sizeof(int));
```

```
    *ptr = 0;
```

```
    while (*ptr < 10) {
```

```
        printf("dereferenced x pointer has value %d\n", *ptr);
```

```
        *ptr = *ptr + 1;
```

```
    }
```

```
    free(ptr);
```

```
    exit(EXIT_SUCCESS);
```

```
}
```

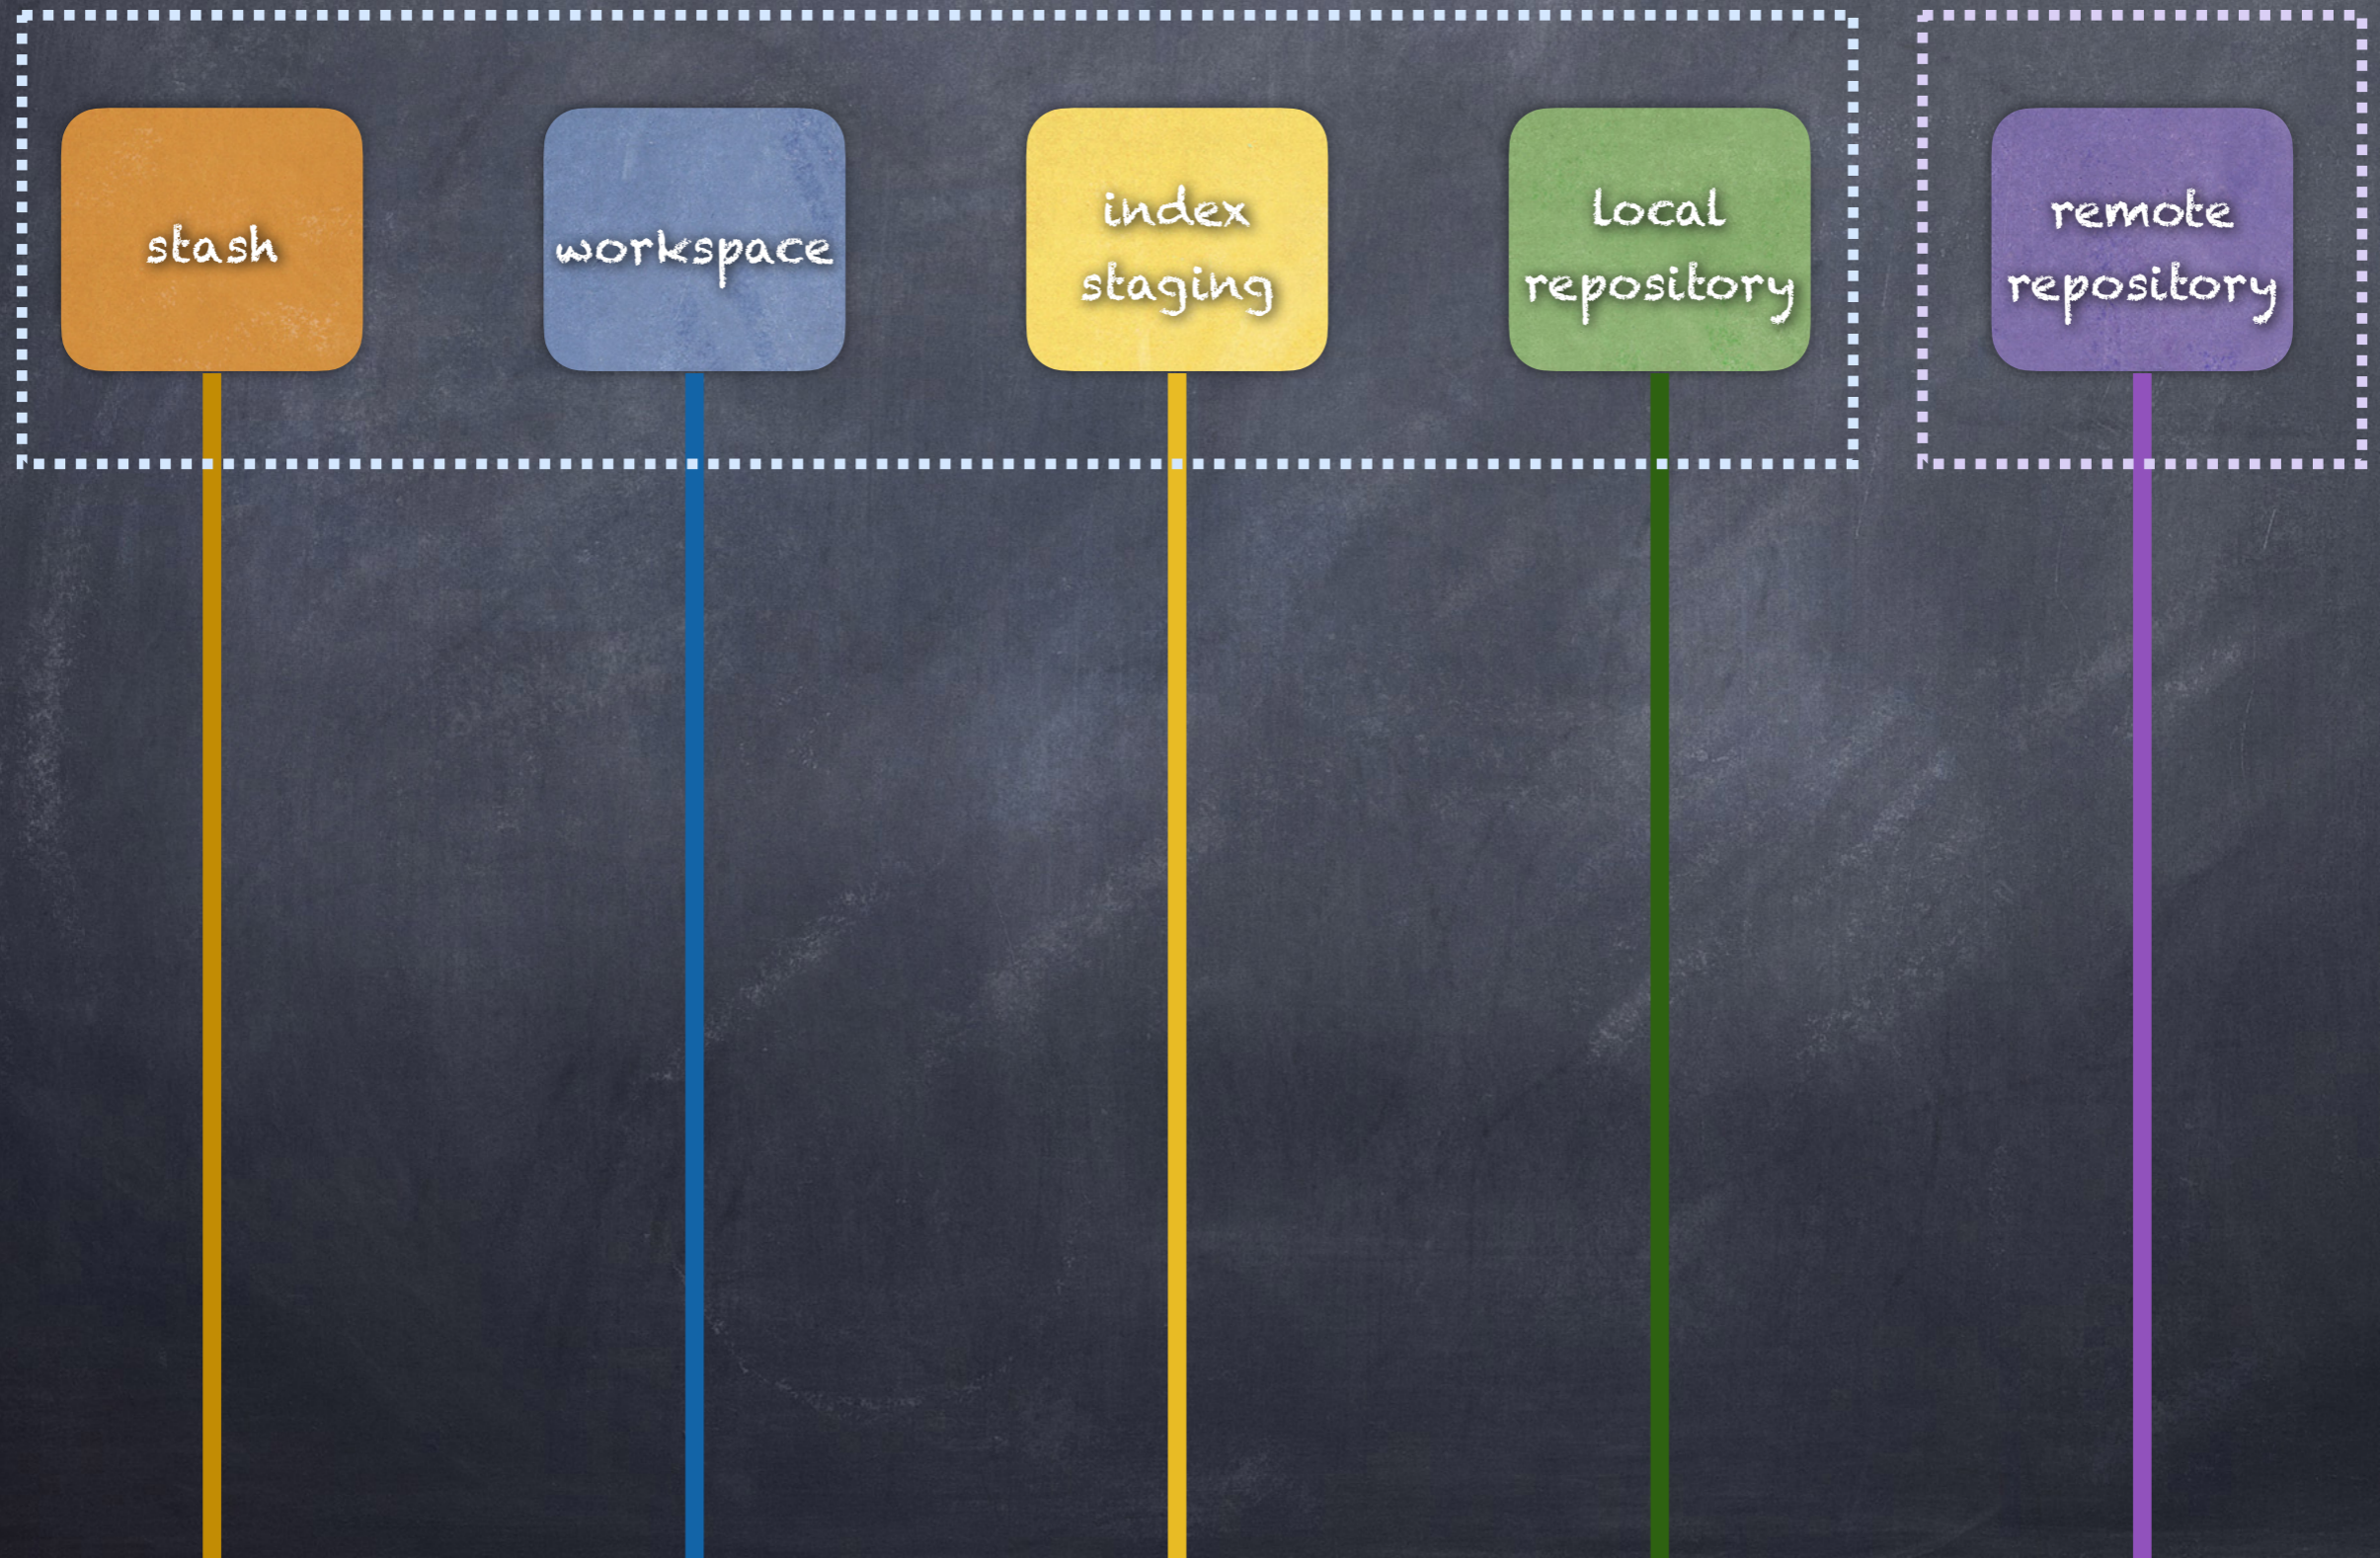

TOPHAT QUESTION

# git

- distributed version control system

Local Machine  
(e.g. your laptop, or  
cerf if you've ssh'ed in)

Remote  
(e.g. bitbucket,  
github,  
CSE servers)

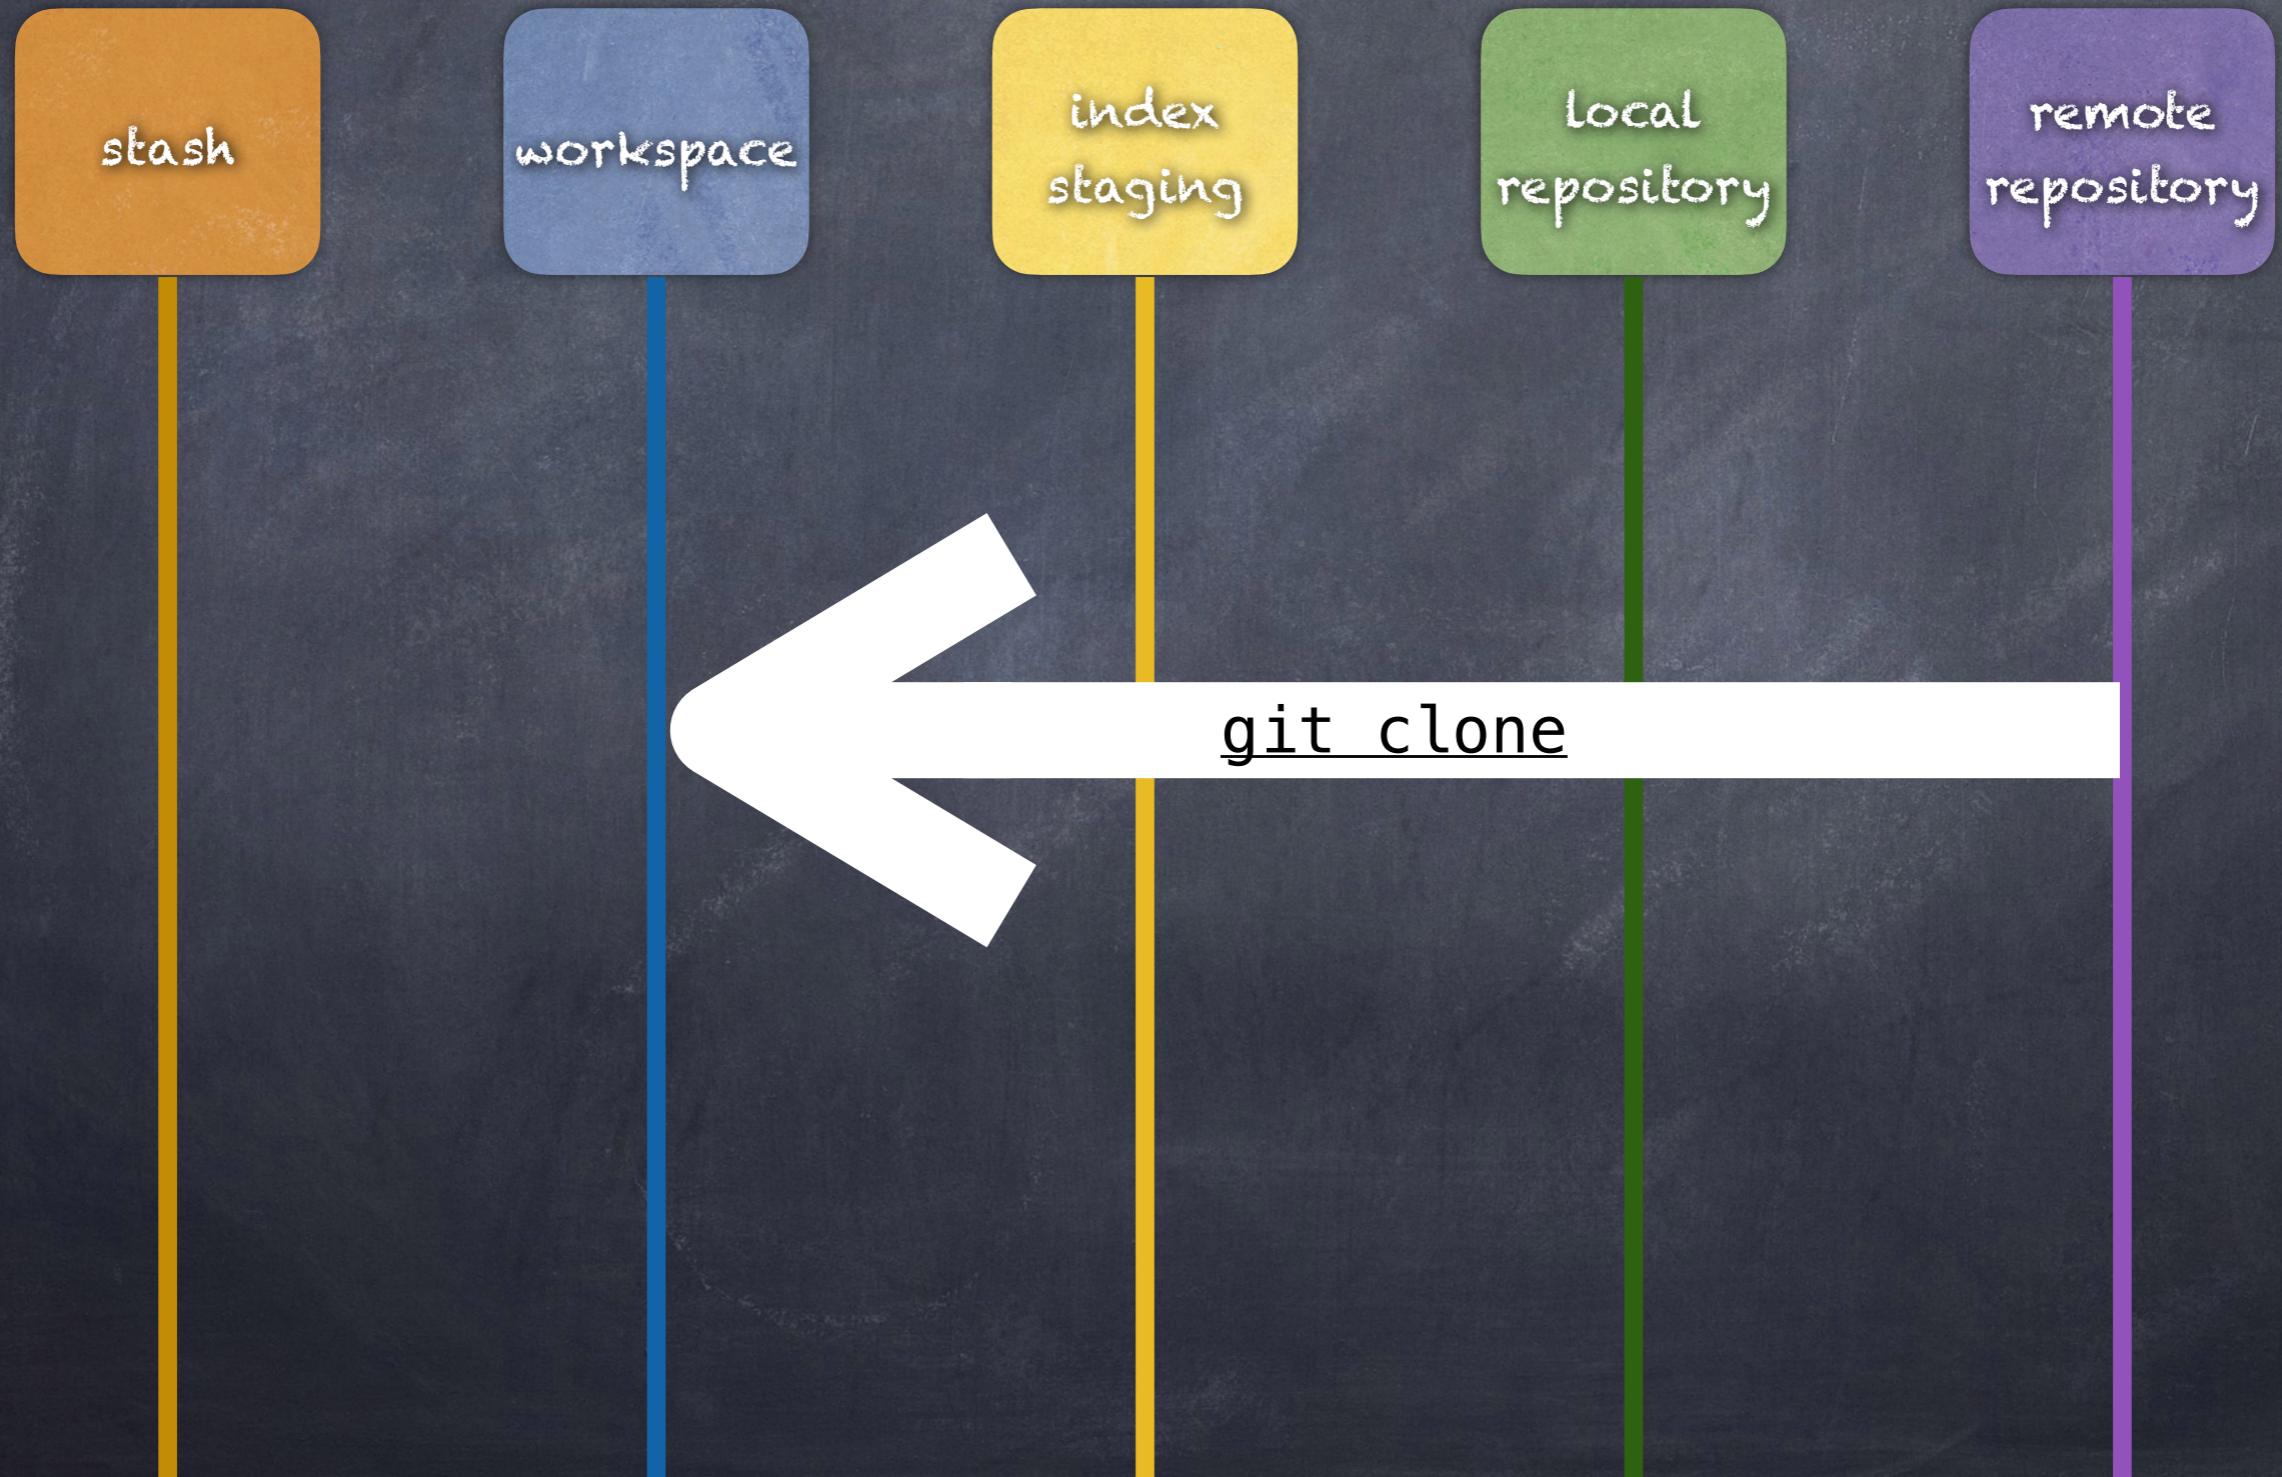

What you see  
when working

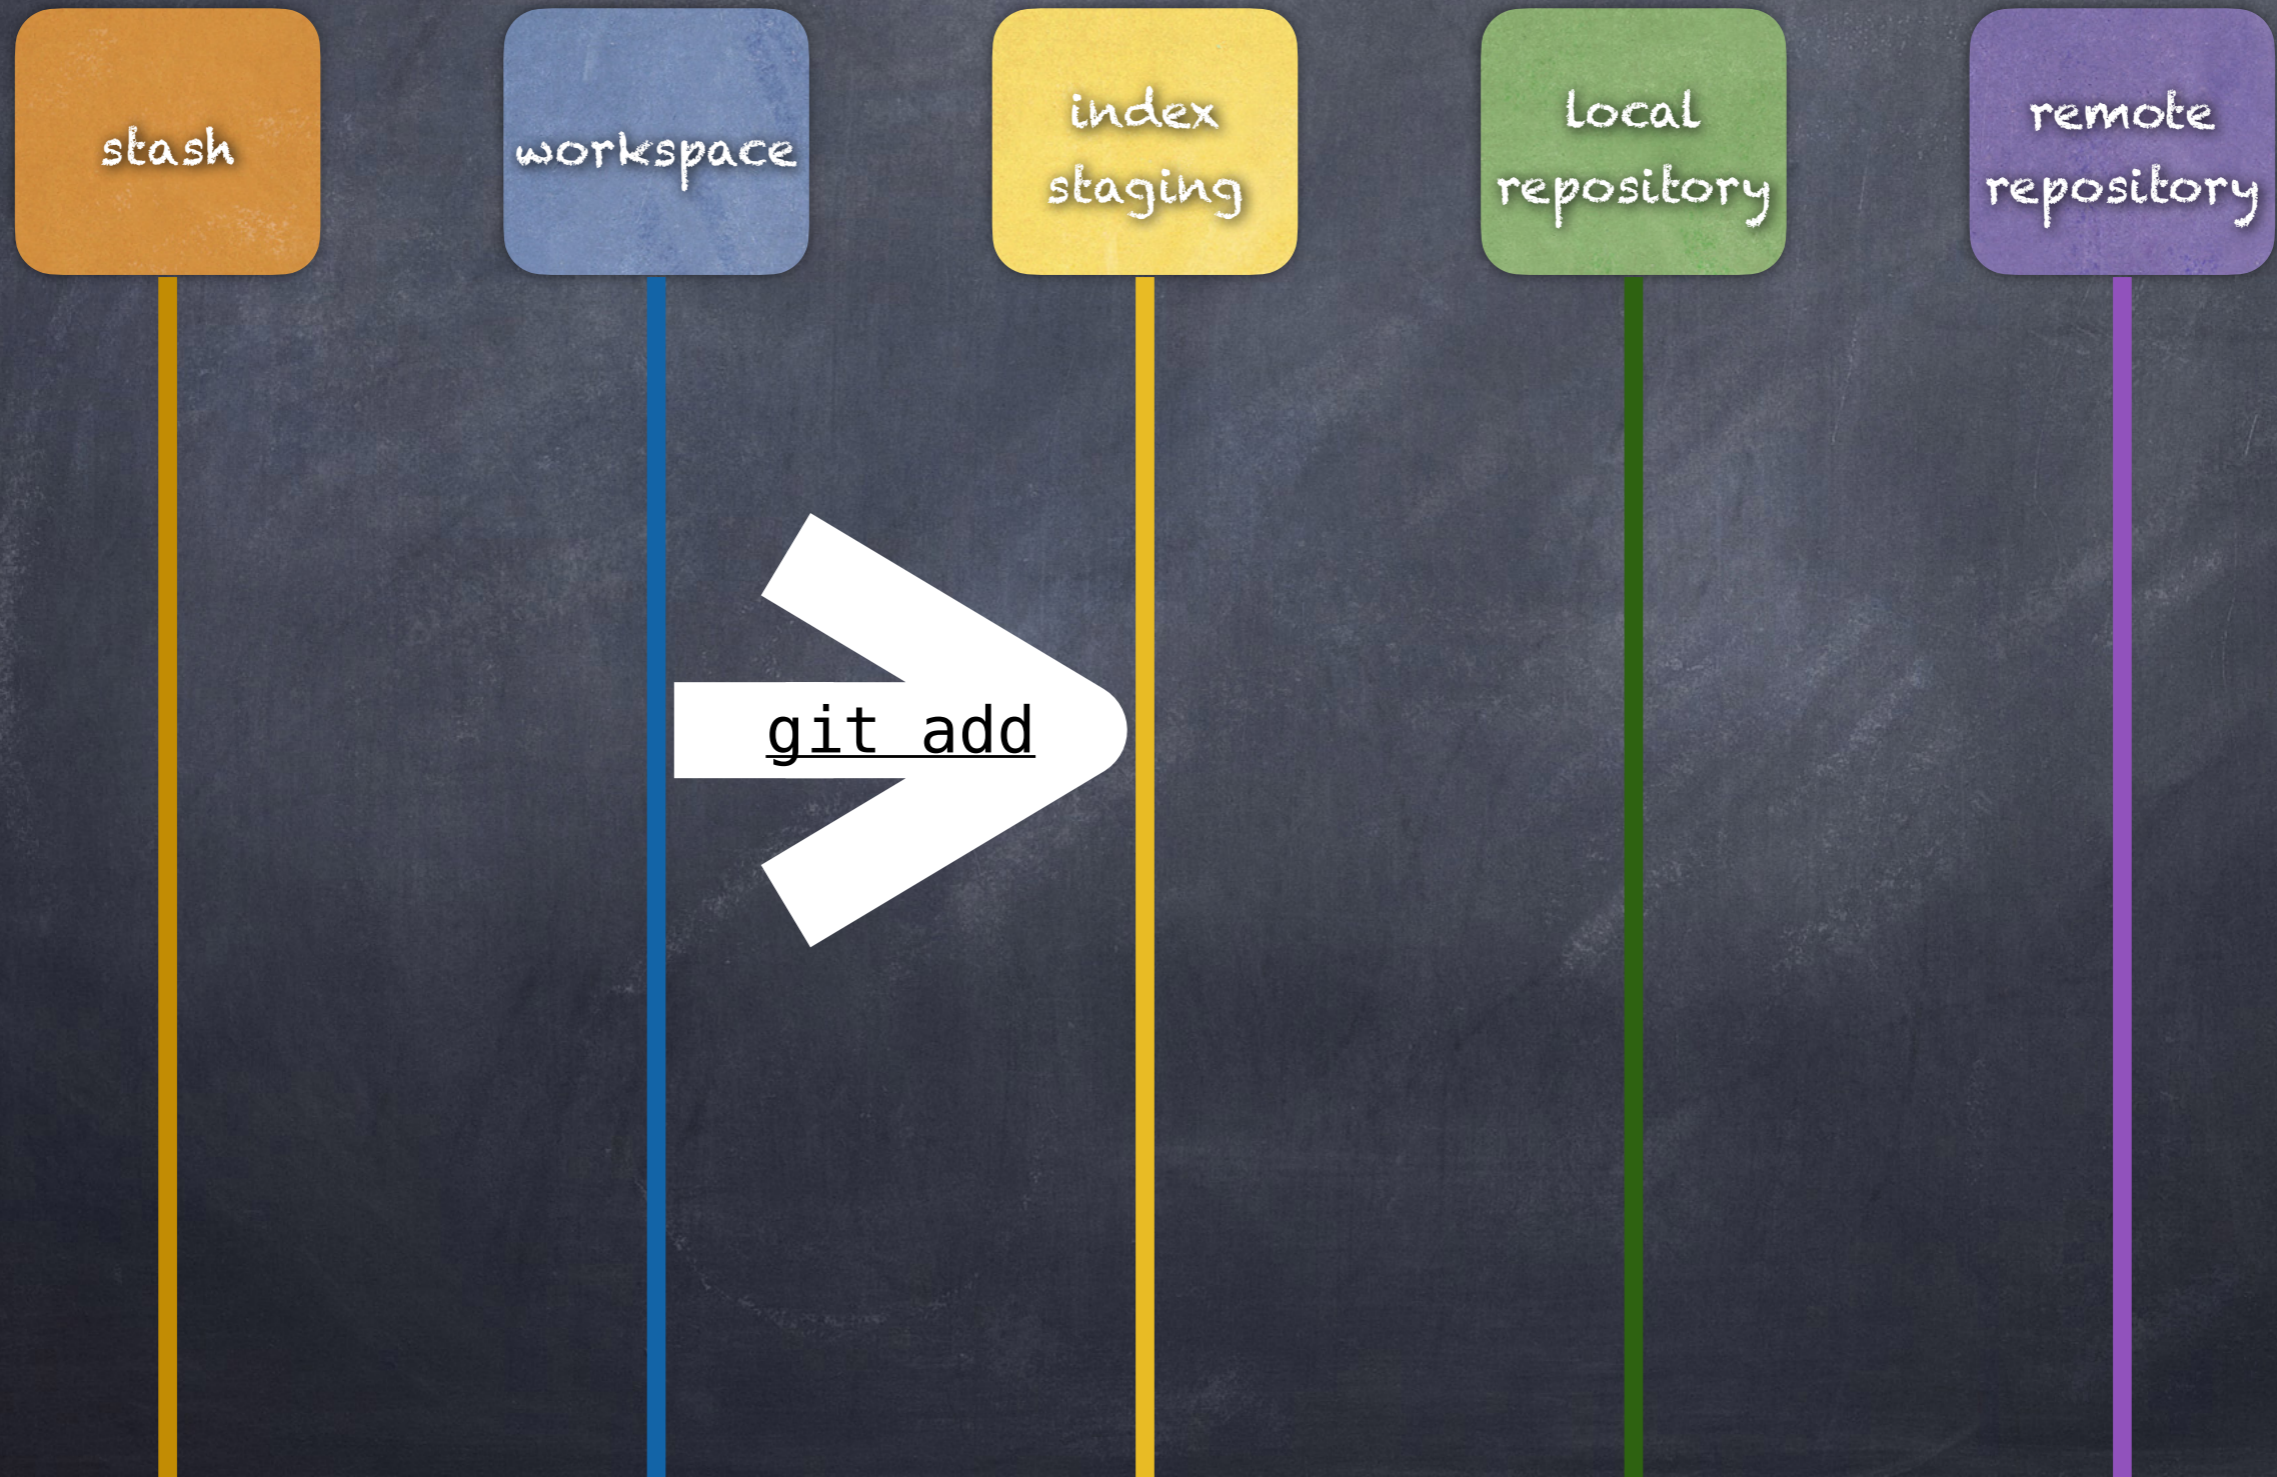

## Cloning a remote

Makes a copy of remote repo in local repo  
and checks out branch into workspace

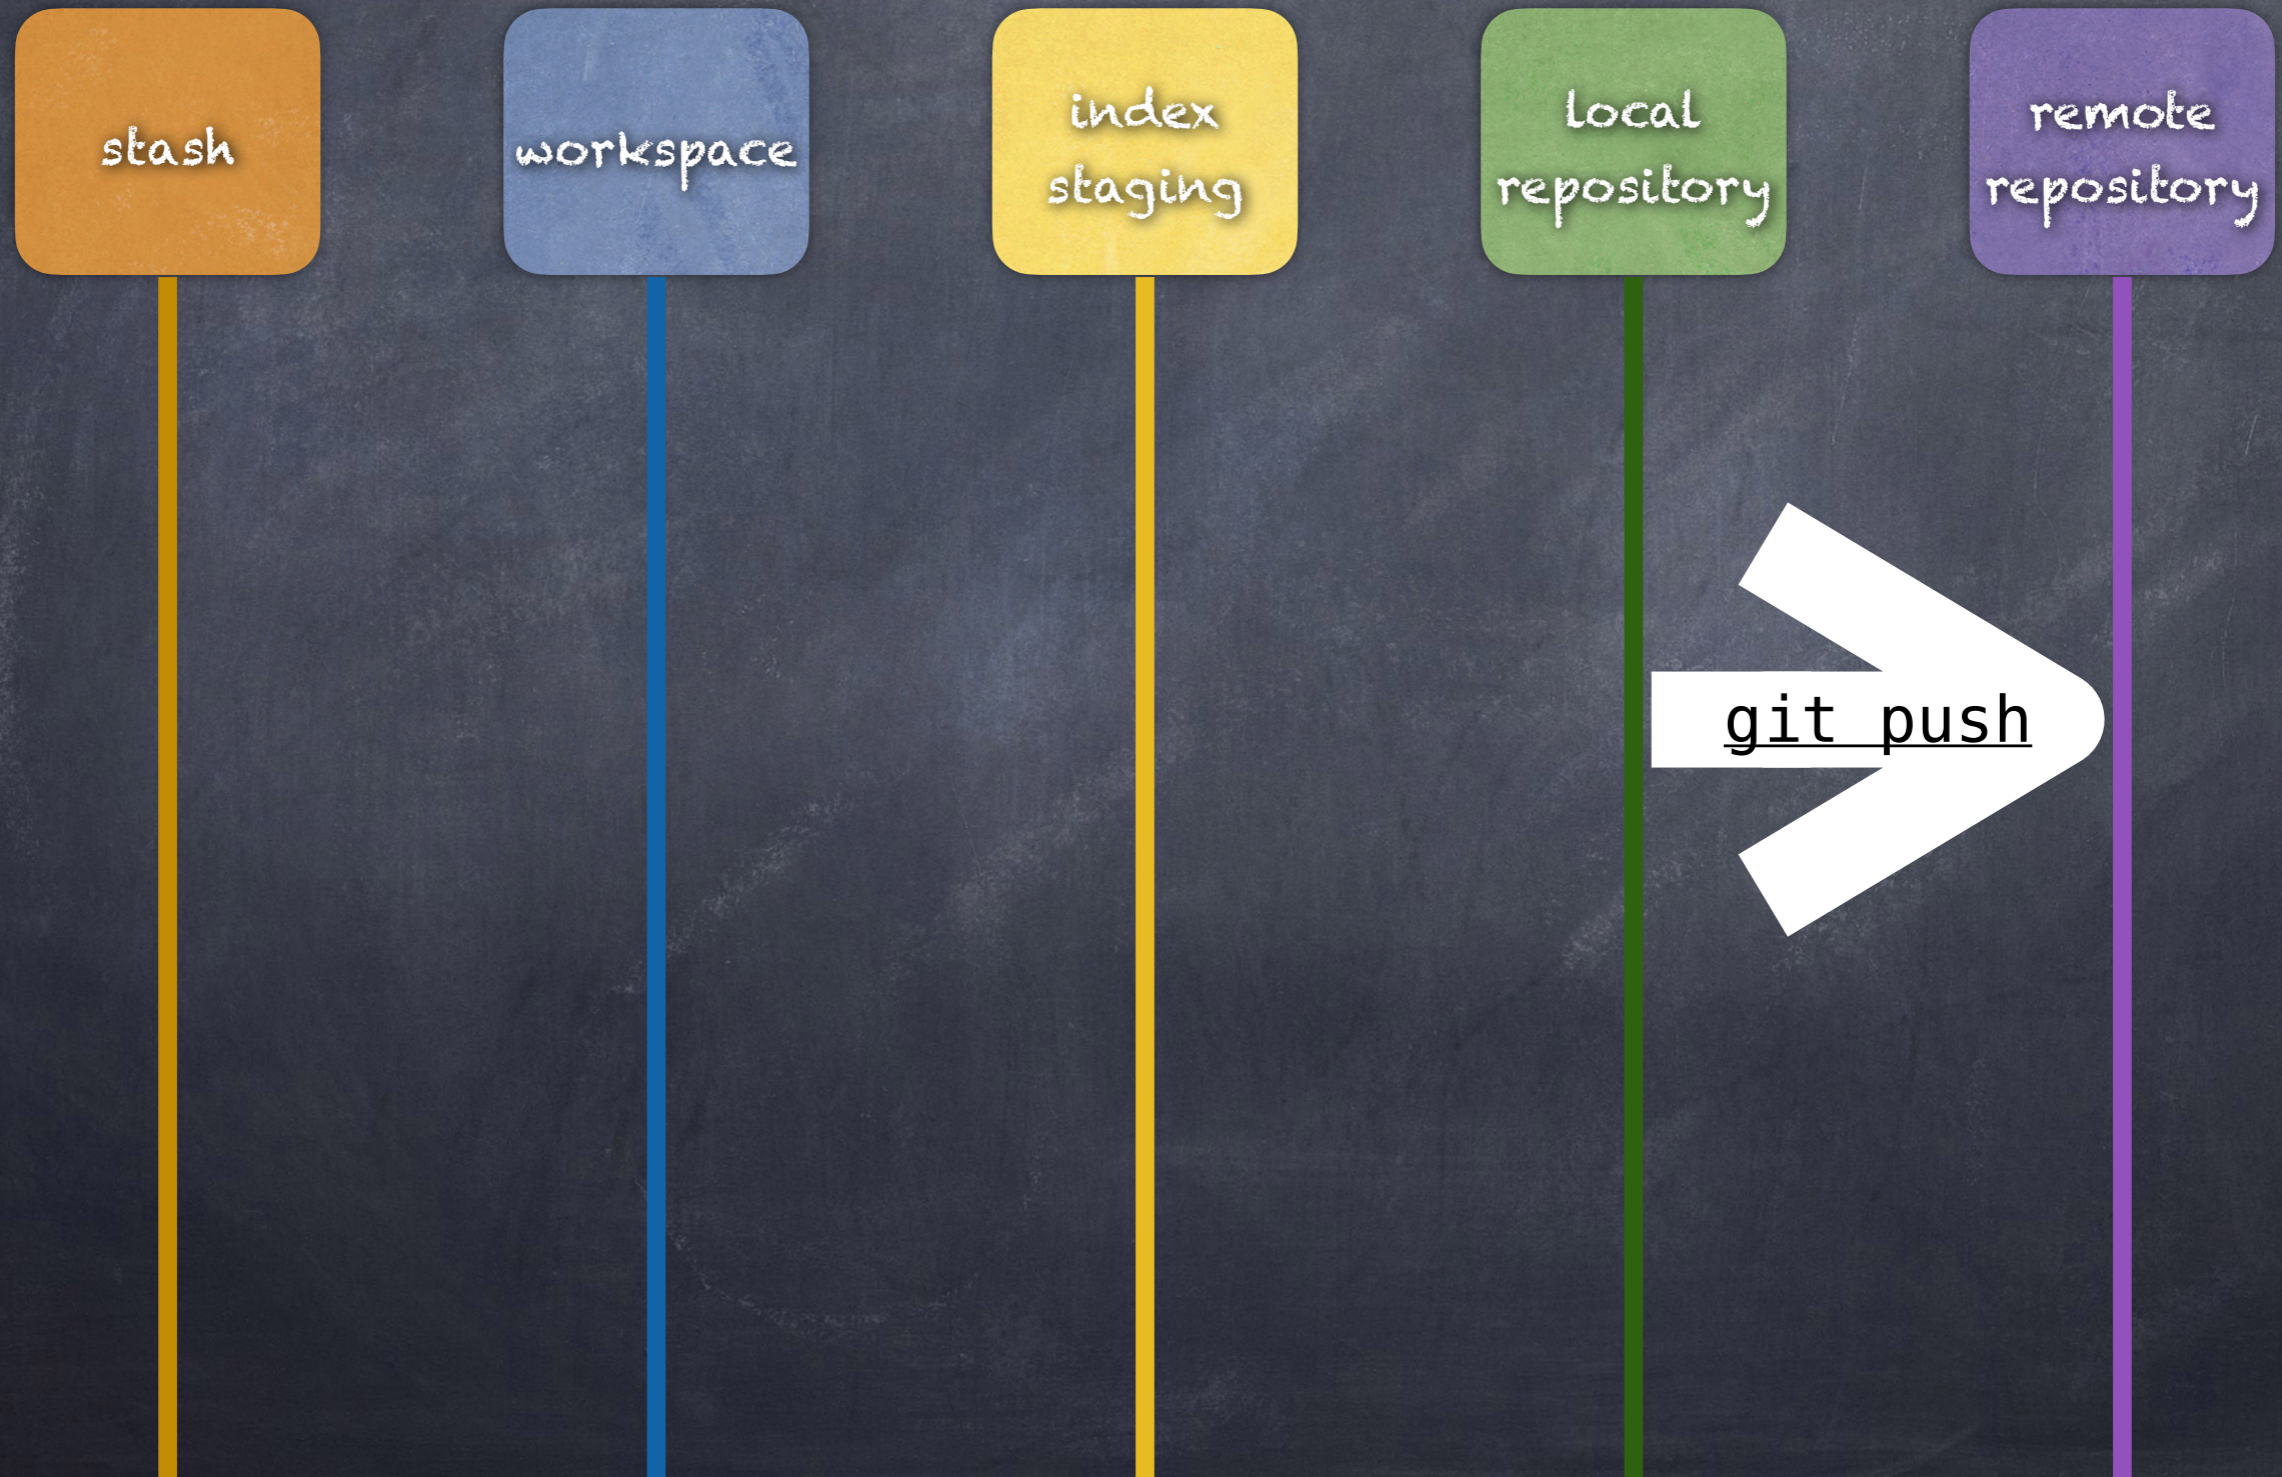

Add a file to the staging area  
(add it to the index)

Create a new commit object with  
the staged items from the index

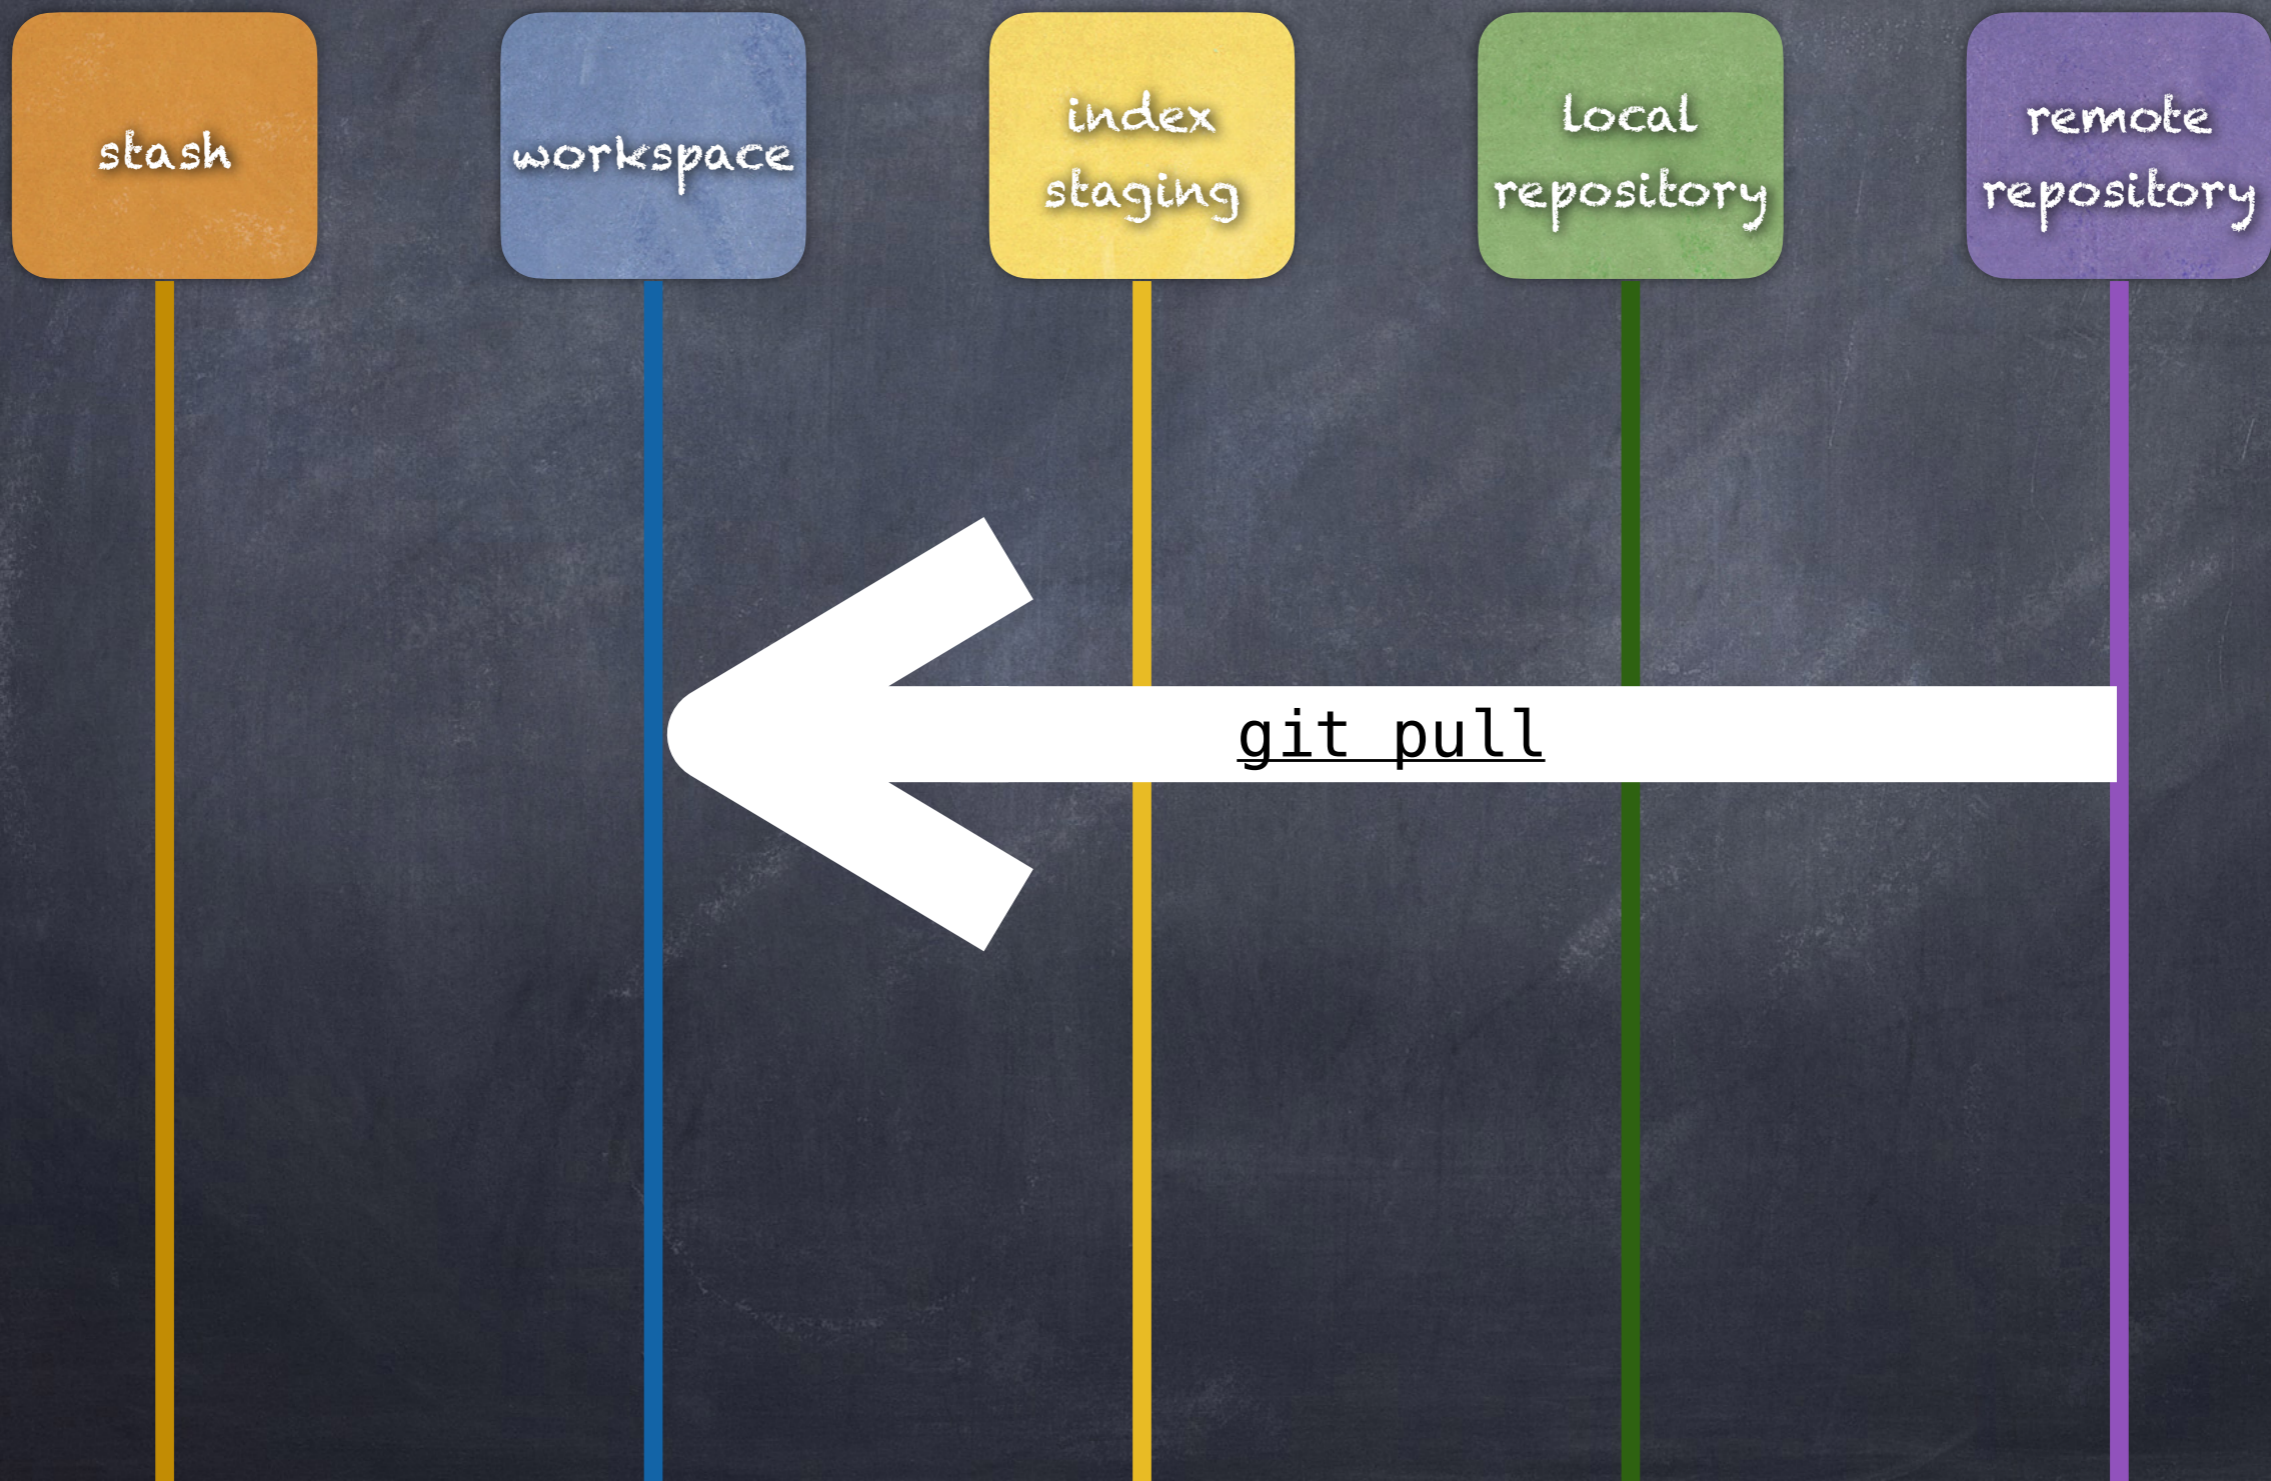

# Push files from local repo to remote repo

# Pulling files

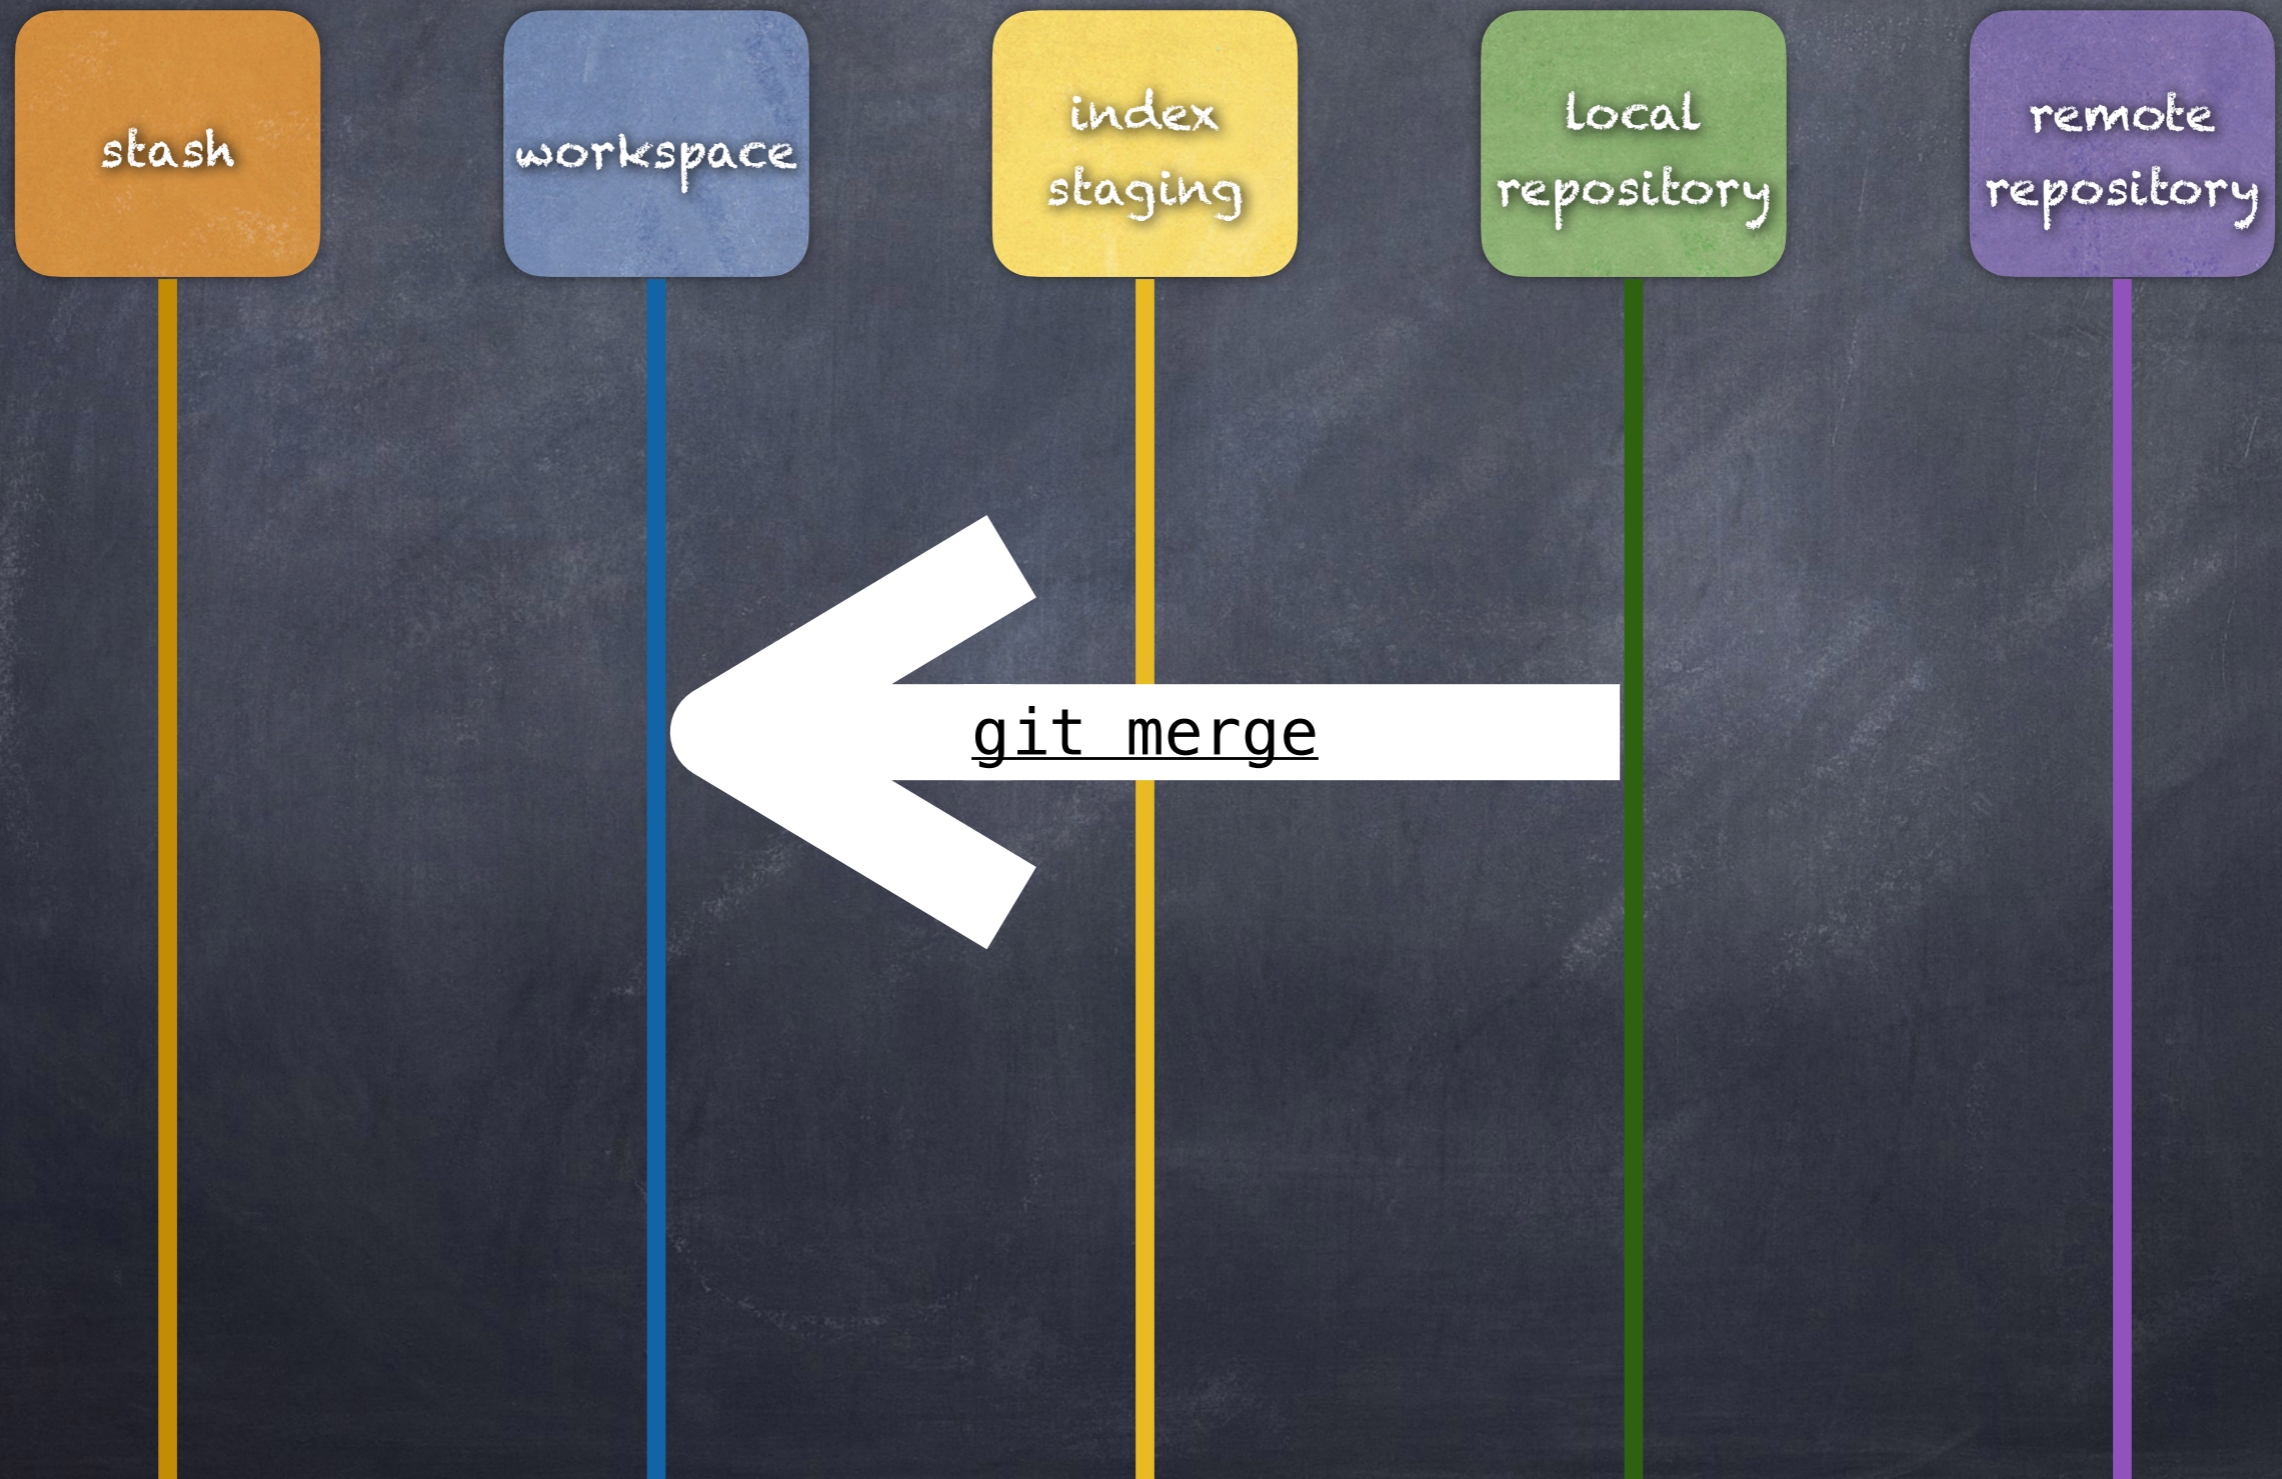

"git pull is shorthand for git fetch followed by git merge FETCH\_HEAD"  
[<https://git-scm.com/docs/git-pull>]

# Grab files from remote

Create a commit combining  
the contents of two branches

# Let's start by cloning an existing repository

# content (blobs, trees, commits)

The [git man page](#) seems to be surprisingly bereft of an official definition, other than this (emphasis mine):

The **object database** contains objects of three main types: **blobs, which hold file data**; trees, which point to blobs and other trees to build up directory hierarchies; and commits, which each reference a single tree and some number of parent commits.

The repeated use of the term "object database" across git documentation suggests a borrowing of "blob" specifically from DBMSs.

In its article on [Binary large objects](#) Wikipedia defines the term as "a collection of binary data stored as a single entity in a database management system", further offering the following:

Blobs were originally just amorphous chunks of data invented by Jim Starkey at DEC, who describes them as "the thing that ate Cincinnati, Cleveland, or whatever" from "the 1958 Steve McQueen movie", referring to The Blob.

Later, Terry McKiever, a marketing person for Apollo, felt that it needed to be an acronym and invented the backronym Basic Large Object. Then Informix invented an alternative backronym, Binary Large Object.

So, though it's not a definitive answer, the term "blob" has a conventional and well-defined usage across computer science as an opaque string of binary data, and git adheres to that definition without further specifying it.

# https://git-scm.com/docs/git-cat-file

## NAME

git-cat-file - Provide contents or details of repository objects

## SYNOPSIS

```
git cat-file <type> <object>
git cat-file (-e | -p) <object>
git cat-file (-t | -s) [--allow-unknown-type] <object>
git cat-file (--textconv | --filters)
    [<rev>:<path|tree-ish> | --path=<path|tree-ish> <rev>]
git cat-file (--batch | --batch-check | --batch-command) [--batch-all-
objects]
    [--buffer] [--follow-symlinks] [--unordered]
    [--textconv | --filters] [-Z]
```

## DESCRIPTION

Output the contents or other properties such as size, type or delta information of one or more objects.

This command can operate in two modes, depending on whether an option from the `--batch` family is specified.

In non-batch mode, the command provides information on an object named on the command line.

In batch mode, arguments are read from standard input.

## OPTIONS

### <object>

The name of the object to show. For a more complete list of ways to spell object names, see the "SPECIFYING REVISIONS" section in [gitrevisions\[7\]](#).

### -t

Instead of the content, show the object type identified by `<object>`.

### -s

Instead of the content, show the object size identified by `<object>`. If used with `--use-mailmap` option, will show the size of updated object after replacing idents using the mailmap mechanism.

### -e

Exit with zero status if `<object>` exists and is a valid object. If `<object>` is of an invalid format, exit with non-zero status and emit an error on stderr.

### -p

Pretty-print the contents of `<object>` based on its type.
