Phases of a compiler

Intermediate Representation (IR): specification and generation

Figure 1.6, page 5 of text
Intermediate Representation (IR)

we'll use IR defined in textbook: the "three address code"
Three address code instructions
(see 6.2.1, pages 364-5)

1. \( x = y \) op z
2. \( x = \) op y         (treat i2r and r2i as unary ops)
3. \( x = y \)
4. goto L
5. if x goto L / ifFalse x goto L
6. if x relop y goto L
7. function calls:
   - param x
   - call p, n
   - y = call p
   - return y
8. \( x = y[i] \) and \( x[i] = y \)
9. \( x = \&y, x = *y, *x = y \)

We'll start with these.

We'll spend significant time on function calls later.

We'll explore these as needed later on.
type information

- What information does a type convey?

- How is type information used during compilation?
type information

What information does a type convey?
- type indicates size
- type indicates storage location
  (a) primitives: either stack or heap
  (b) records: on heap (via pointer)
  (c) arrays: on heap (via pointer)
  (d) functions: code in static, locals on stack

How is type information used during compilation?
type information

What information does a type convey?
- type indicates size
- type indicates storage location
  (a) primitives: either stack or heap
  (b) records: on heap (via pointer)
  (c) arrays: on heap (via pointer)
  (d) functions: code in static, locals on stack

How is type information used during compilation?
- determines how to lay out records, arrays, invocation records in memory
- determines how to translate names in program to memory accesses
- determines which instructions to use to manipulate values in memory
Sizes of types

- int: 32 bits (2's complement)
- real: 64 bits (IEEE 754)
- Boolean: 8 bits (TBD: machine dependent)
- character: 8 bit (ASCII)
Sizes/layouts of values of types

- type string: 1 → character
  - 4 bytes + length of string * size of character (= 1 byte)
- # of dimensions is part of type

<table>
<thead>
<tr>
<th>size of dimension 1 (integer)</th>
<th>(0)</th>
<th>(1)</th>
<th>(2)</th>
<th>(3)</th>
<th>(4)</th>
</tr>

Array layout in memory

Two options:

- row-major
- column-major

Textbook discusses on page 382; row-major and column-major refer to two-dimensional arrays, but can be generalized for arrays with more dimensions.
# Row-major array layout

What is the size of an X-dimensional array of type T?

Sizes of dimensions \((S_i)\): X * 4 bytes

Data: \((\prod_{i \in X} S_i) \times \text{sizeOf}(T)\)

(plus padding for real to get to proper boundary)

Example shows two-dimensional array (2 rows, 3 columns)

<table>
<thead>
<tr>
<th>size of first dimension</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>size of second dimension</td>
<td>2</td>
</tr>
<tr>
<td>a(0,0)</td>
<td></td>
</tr>
<tr>
<td>a(0,1)</td>
<td></td>
</tr>
<tr>
<td>a(0,2)</td>
<td></td>
</tr>
<tr>
<td>first row</td>
<td></td>
</tr>
<tr>
<td>a(1,0)</td>
<td></td>
</tr>
<tr>
<td>a(1,1)</td>
<td></td>
</tr>
<tr>
<td>a(1,2)</td>
<td></td>
</tr>
<tr>
<td>second row</td>
<td></td>
</tr>
</tbody>
</table>

Column-major array layout

What is the size of an \(X\)-dimensional array of type \(T\)?

Sizes of dimensions \((S_i)\): \(X\times4\) bytes

data: \((T_{i\in X} S_i) \times \text{sizeof}(T)\)

Example shows two-dimensional array (2 rows, 3 columns)
Propagation of type information in parse tree
Figure 6.16, p 375

For the purposes of type checking the number of dimensions is relevant, but the size of each dimension is not.
Figure 6.16, p. 375

What if type info comes after dimensions?

For alpha, add space for size of each dimension

$8 + \text{array}(2, \text{arr}(3, \text{character}))$

$w = 8 + 6 \times 1 = 14$

$w = 2 \times 3$

$w = 6$

$w = 3$

Character

$w = 1$

$\epsilon$

For alpha, add space for size of each dimension

What if type info comes after dimensions?
Planting a seed...

Q: if a and b are compatible array types, what are the semantics of a := b?
Planting a seed...

Q: if a and b are compatible array types, what are the semantics of a := b ?

A: We won't answer this now, but think about it...
Variables and memory

- Variables have names in our high level programs.
- Names don't exist at runtime.
- Variables are allocated space in a block of memory.
  - Local variables have space in a stack frame (a.k.a. invocation record).
  - Array cells and record members have space in heap-allocated block of memory.
Variables and memory

- Every use of a variable is translated into an address by the compiler...
  ...but not an absolute address - we have no idea where in memory things will be loaded!

- For every allocated block of memory there is a base/reference address.

- Variables housed within each block have a location in the block that is relative to the base/reference address.
Variables and memory

- The relative address is expressed as an offset from the base/reference address.

- The offset is determined by
  - where other variables in the block are located,
  - how much space is needed to hold the variable's type of value, and
  - whether or not we need to align the starting address on a specific boundary.
Arrays

What is the size of a multi-dimensional array of type T?

sizes of dimensions ($S_i$): $X \times 4$ bytes

data: $\prod_{i \in X} S_i \times \text{sizeof}(T)$

assume sizeof(T) is 1

address for size of second dimension (and offset 0)

address for size of first dimension

base address and offset (0) for size of first dimension

address for a(0,0): offset 8
address for a(0,1): offset 9
address for a(0,2): offset 10
address for a(1,0): offset 11
etc.

<table>
<thead>

Since declarations must be gathered together at the start of a sblock, and cannot themselves be directly nested, we can do better:

```
dblock:: {  (  integer :  x  ,  y  )
{ (  real :  x  ,  z  ) … … }
{ (  Boolean :  y  ; character : z   )
… …
}
```

records (in separate symbol table), sequence of declarations at start of sblock

AT RUNTIME
**dblocks (6.3.5 and 6.3.6)**

Records (in separate symbol table), sequence of declarations at start of sblock.

Since declarations must be gathered together at the start of an sblock, and cannot themselves be directly nested, we can do better:

```plaintext
dblock → '['
{ Env.push(st); st = new Env(); Stack.push(offset); offset = 0; } declaration-list ']'
{ dblock.type=record(st); dblock.width=offset; st=Env.pop(); offset=Stack.pop(); }
```

**AT RUNTIME**

```
integer: x
integer: y
real: x
real: z
```
dblocks (6.3.5 and 6.3.6)

records (in separate symbol table), sequence of declarations at start of sblock

Since declarations must be gathered together at the start of an sblock, and cannot themselves be directly nested, we can do better:

dblock → ']'

{ Env.push(st); st = new Env(); Stack.push(offset); offset = 0; }

declaration-list ']

{ dblock.type=record(st); dblock.width=offset; st=Env.pop(); offset=Stack.pop(); }

At runtime:

push offset = 8 onto stack

push offset = 8 from stack

push offset = 8 onto stack

pop offset = 8 from stack

push offset = 8

...
dblocks (6.3.5 and 6.3.6)
records (in separate symbol table), sequence of declarations at start of sblock
