

A Parallel Algorithm For Maximal Clique Detection

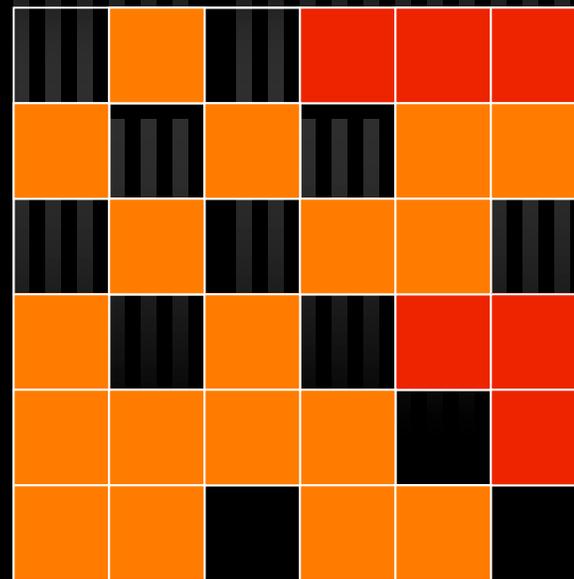

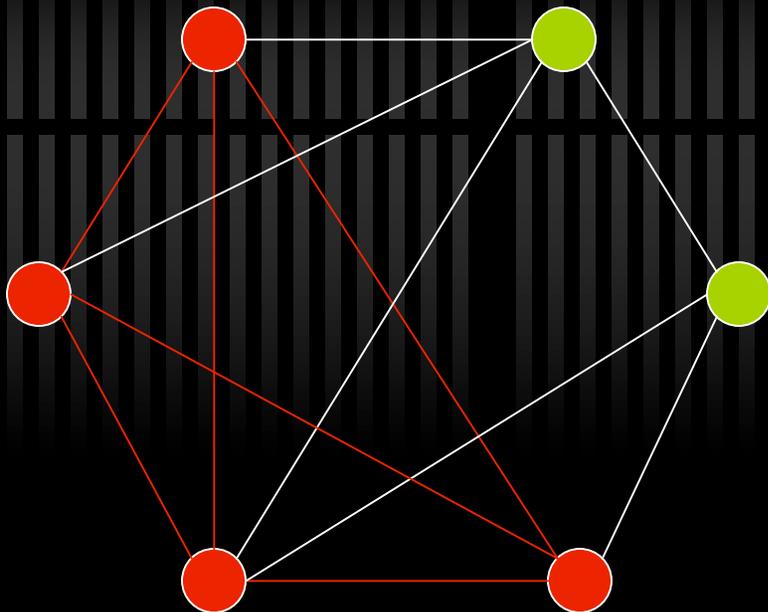

By Steven Kapturowski

CSE 633, Spring 2009

The Problem

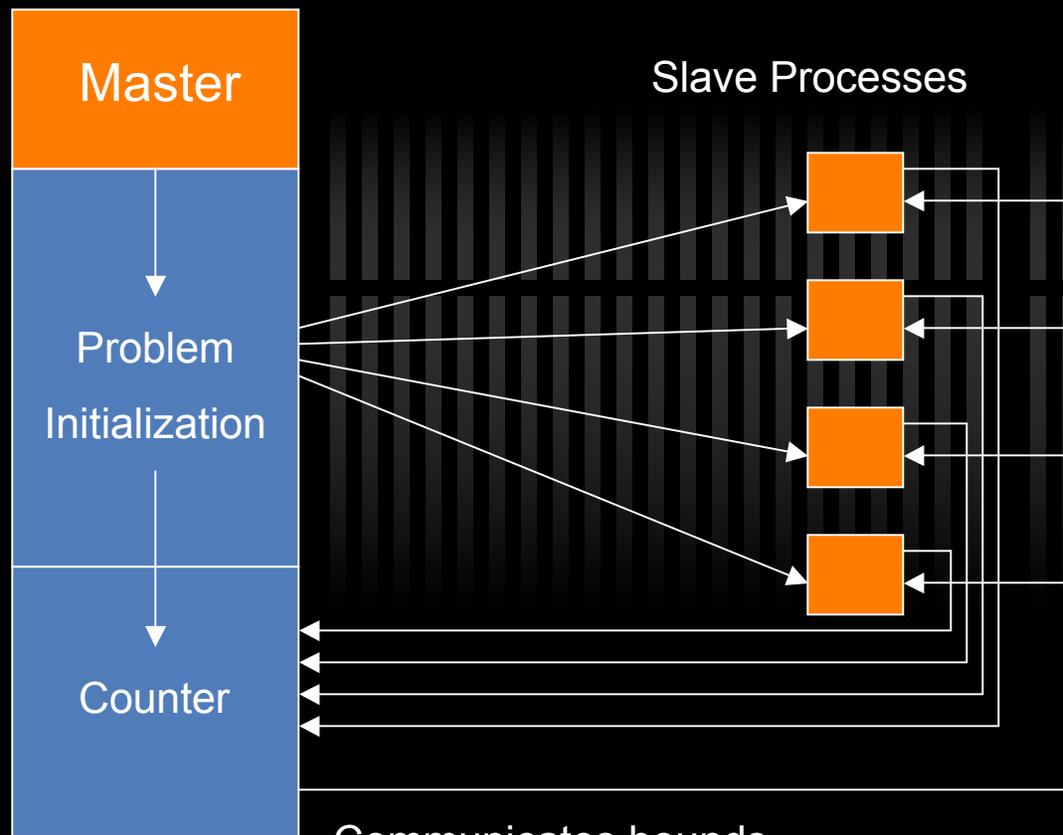

The Problem

The Sequential Solution

- ✓ We enumerate through all graphs of size $n = 3$ and check for completeness
- ✓ For each complete graph check all graphs of size $n+1$ in which it is included
 - Note: we only need to check nodes greater than the highest value in complete graph!
- ✓ Repeat Step 2

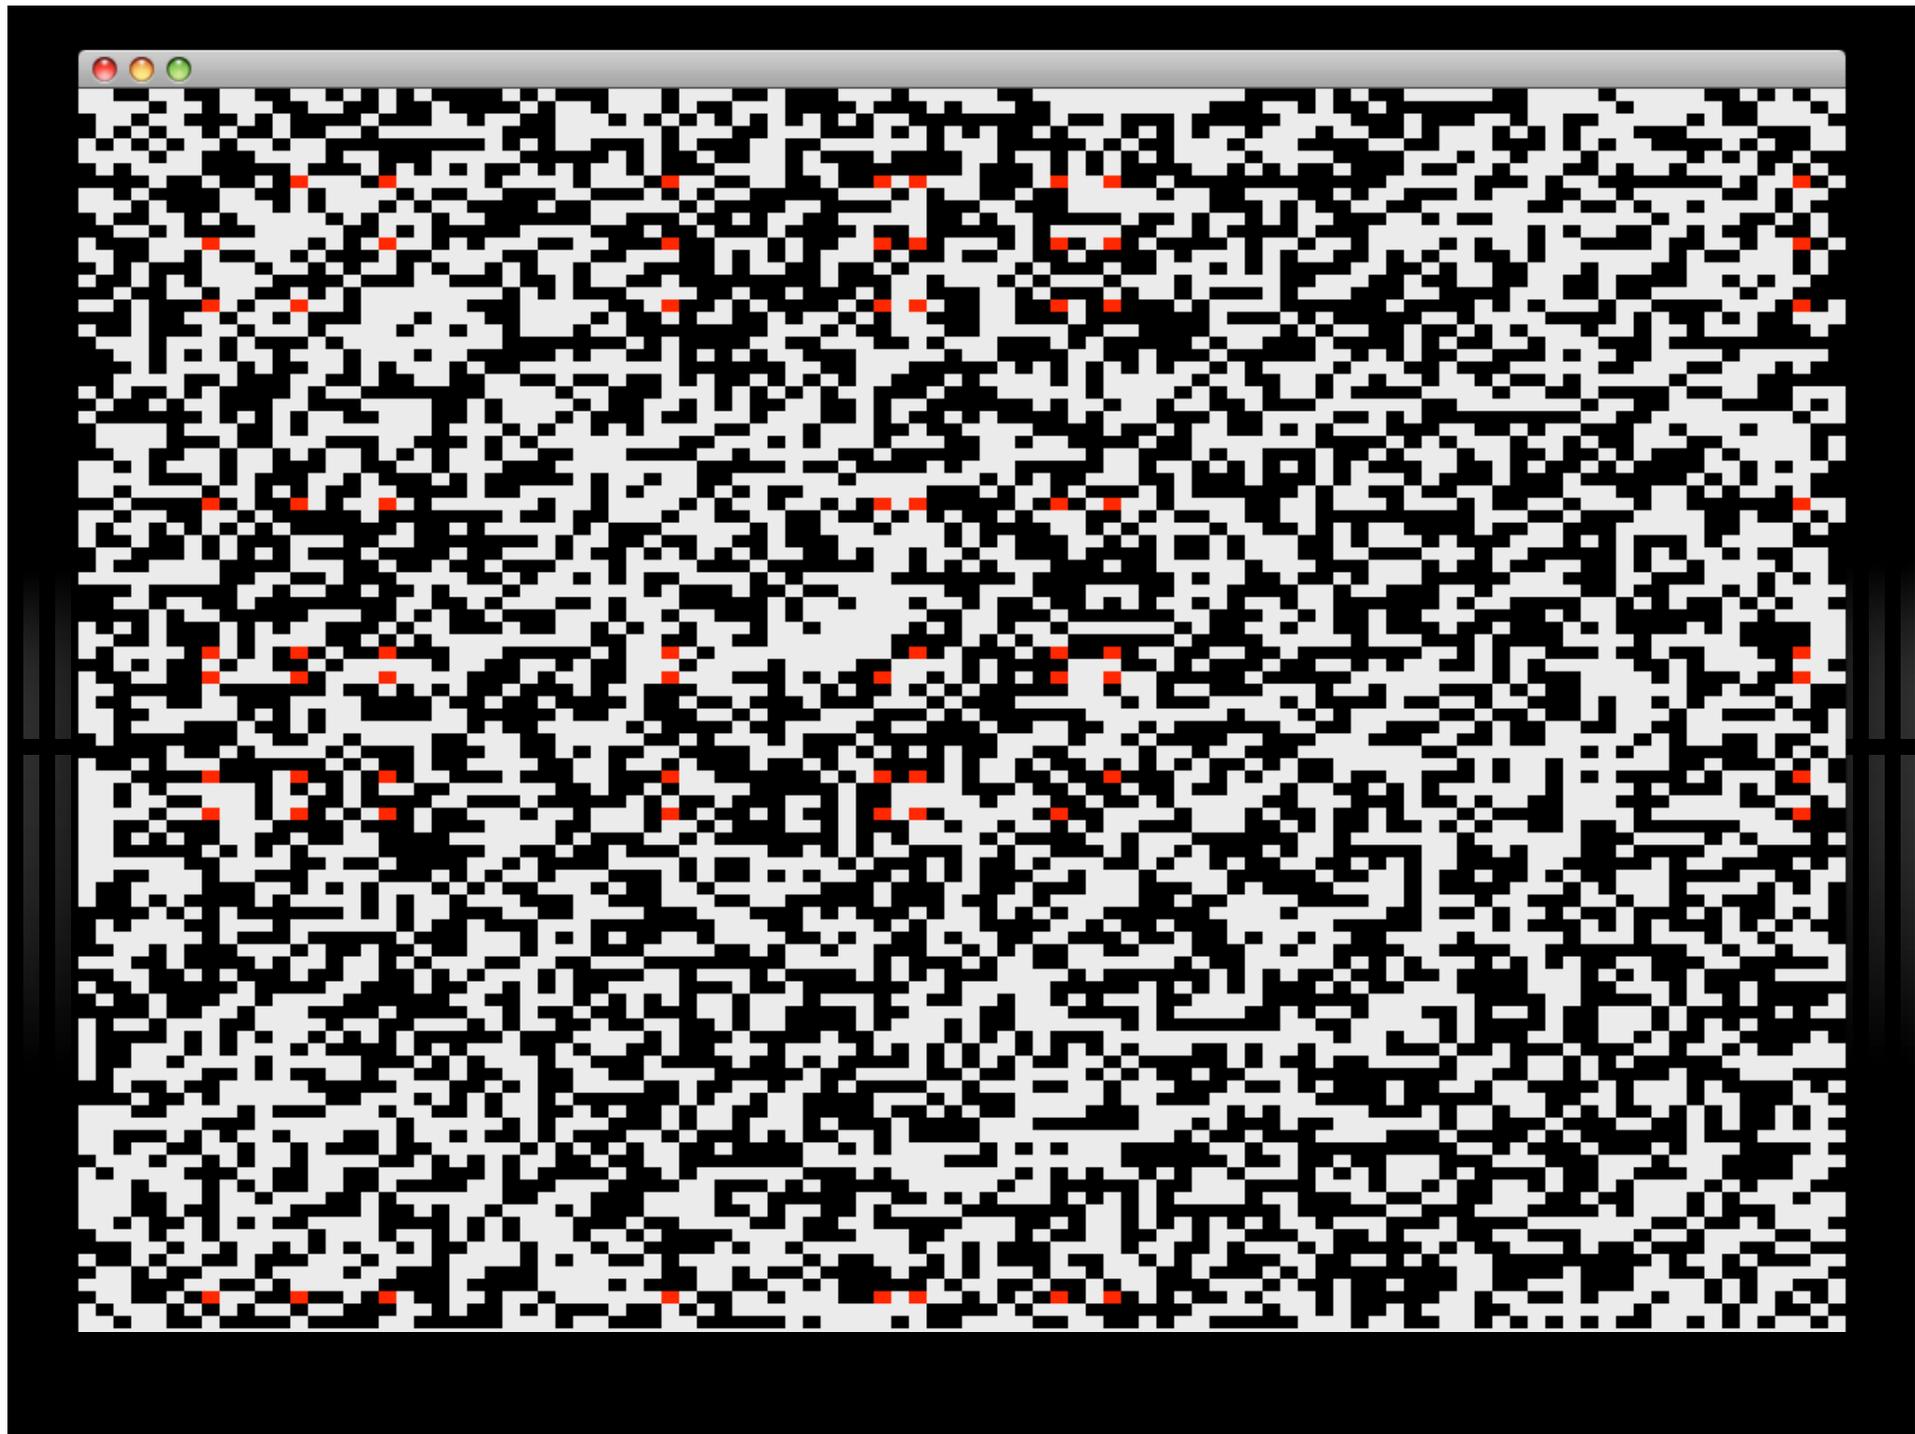

Parallel Solution

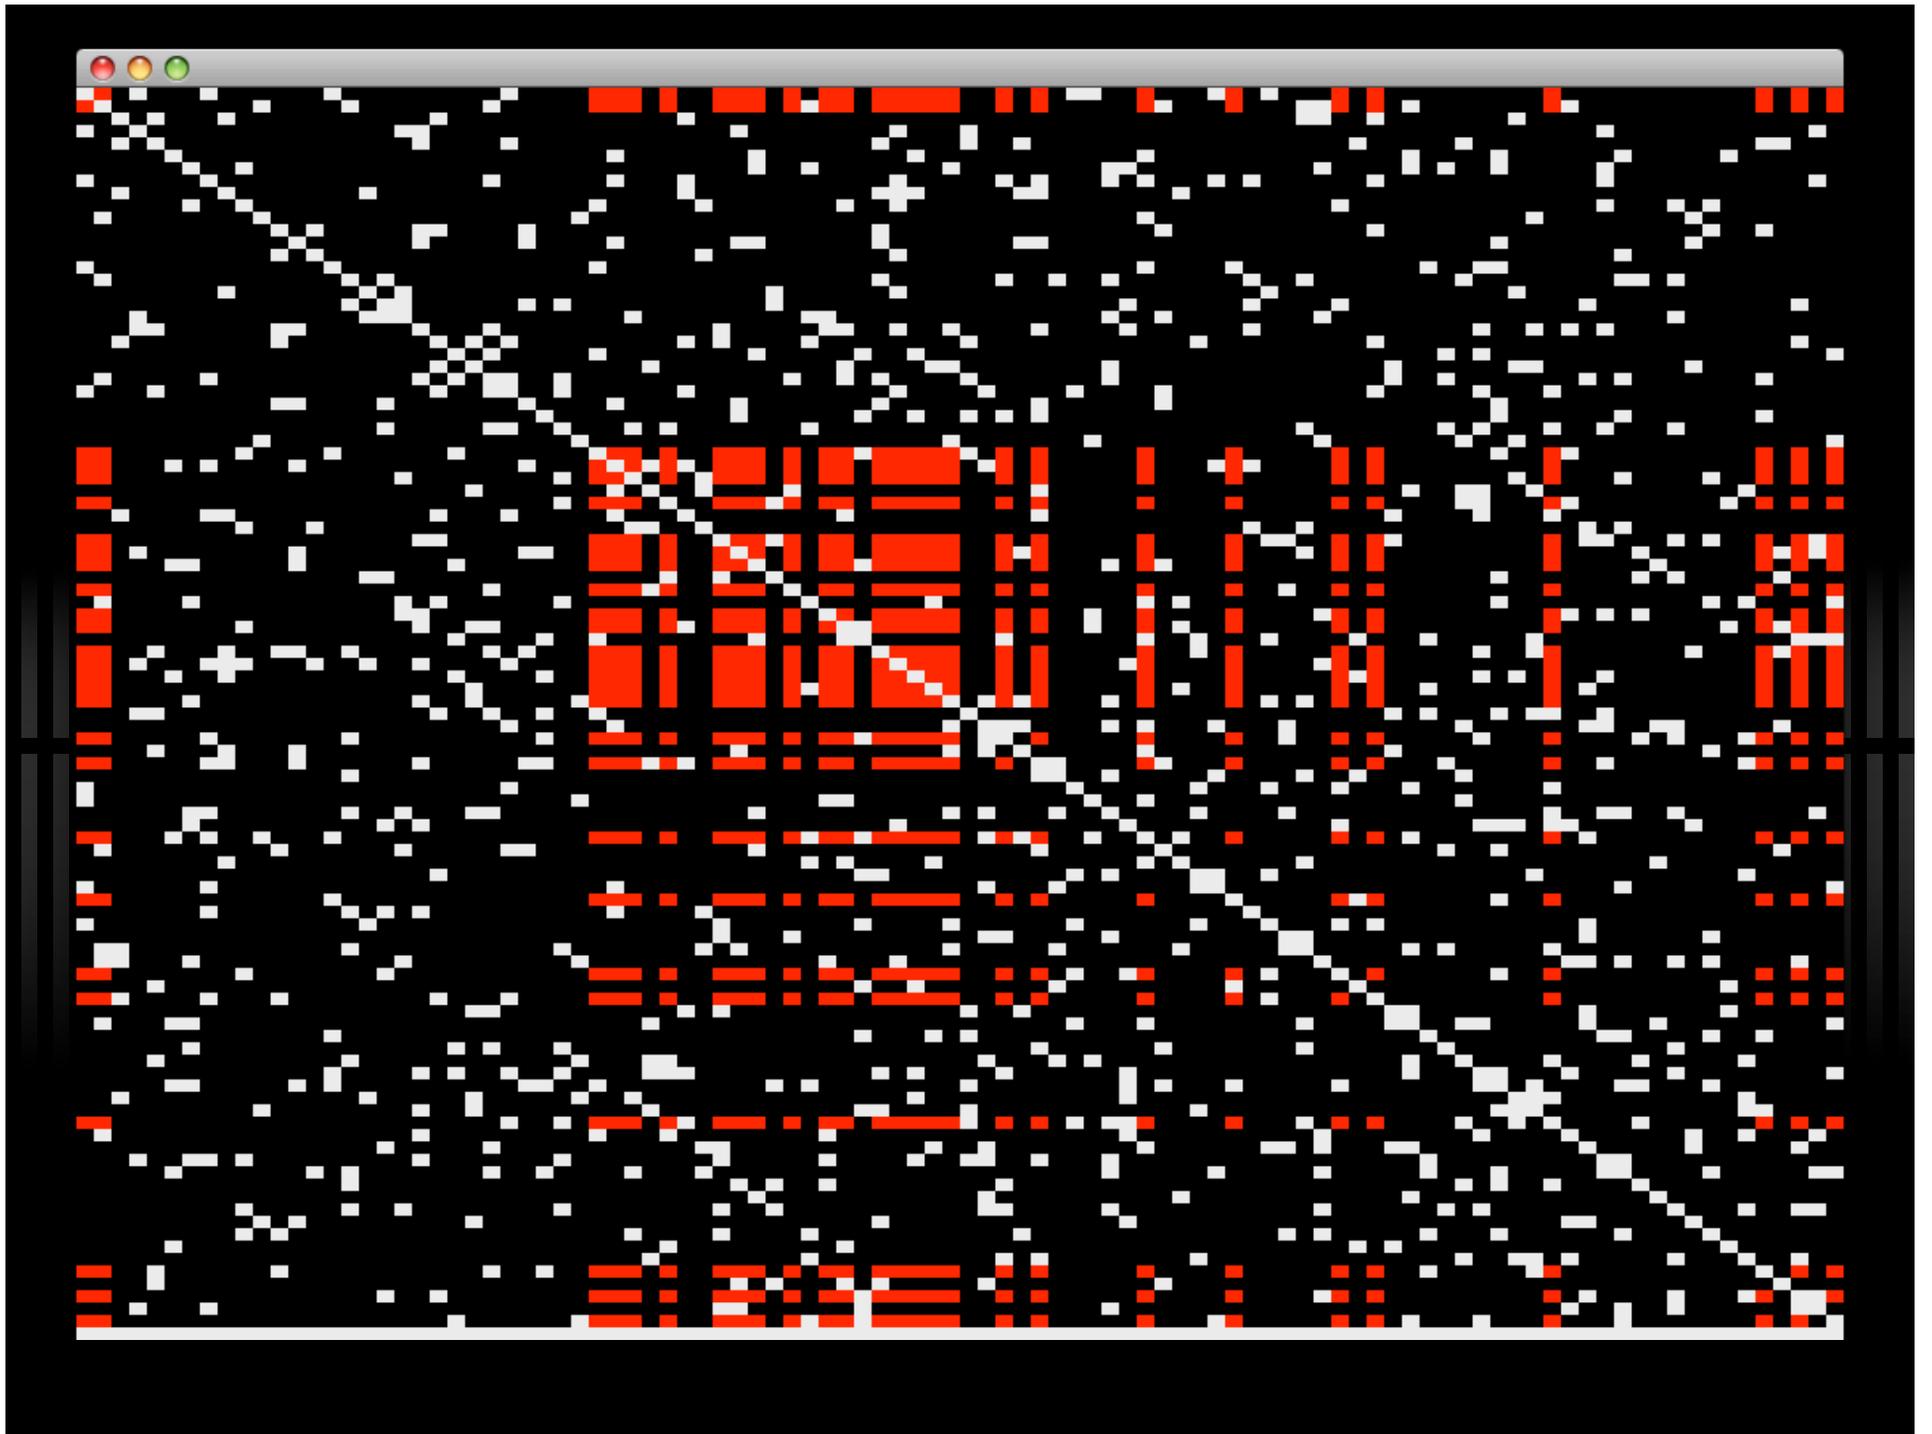

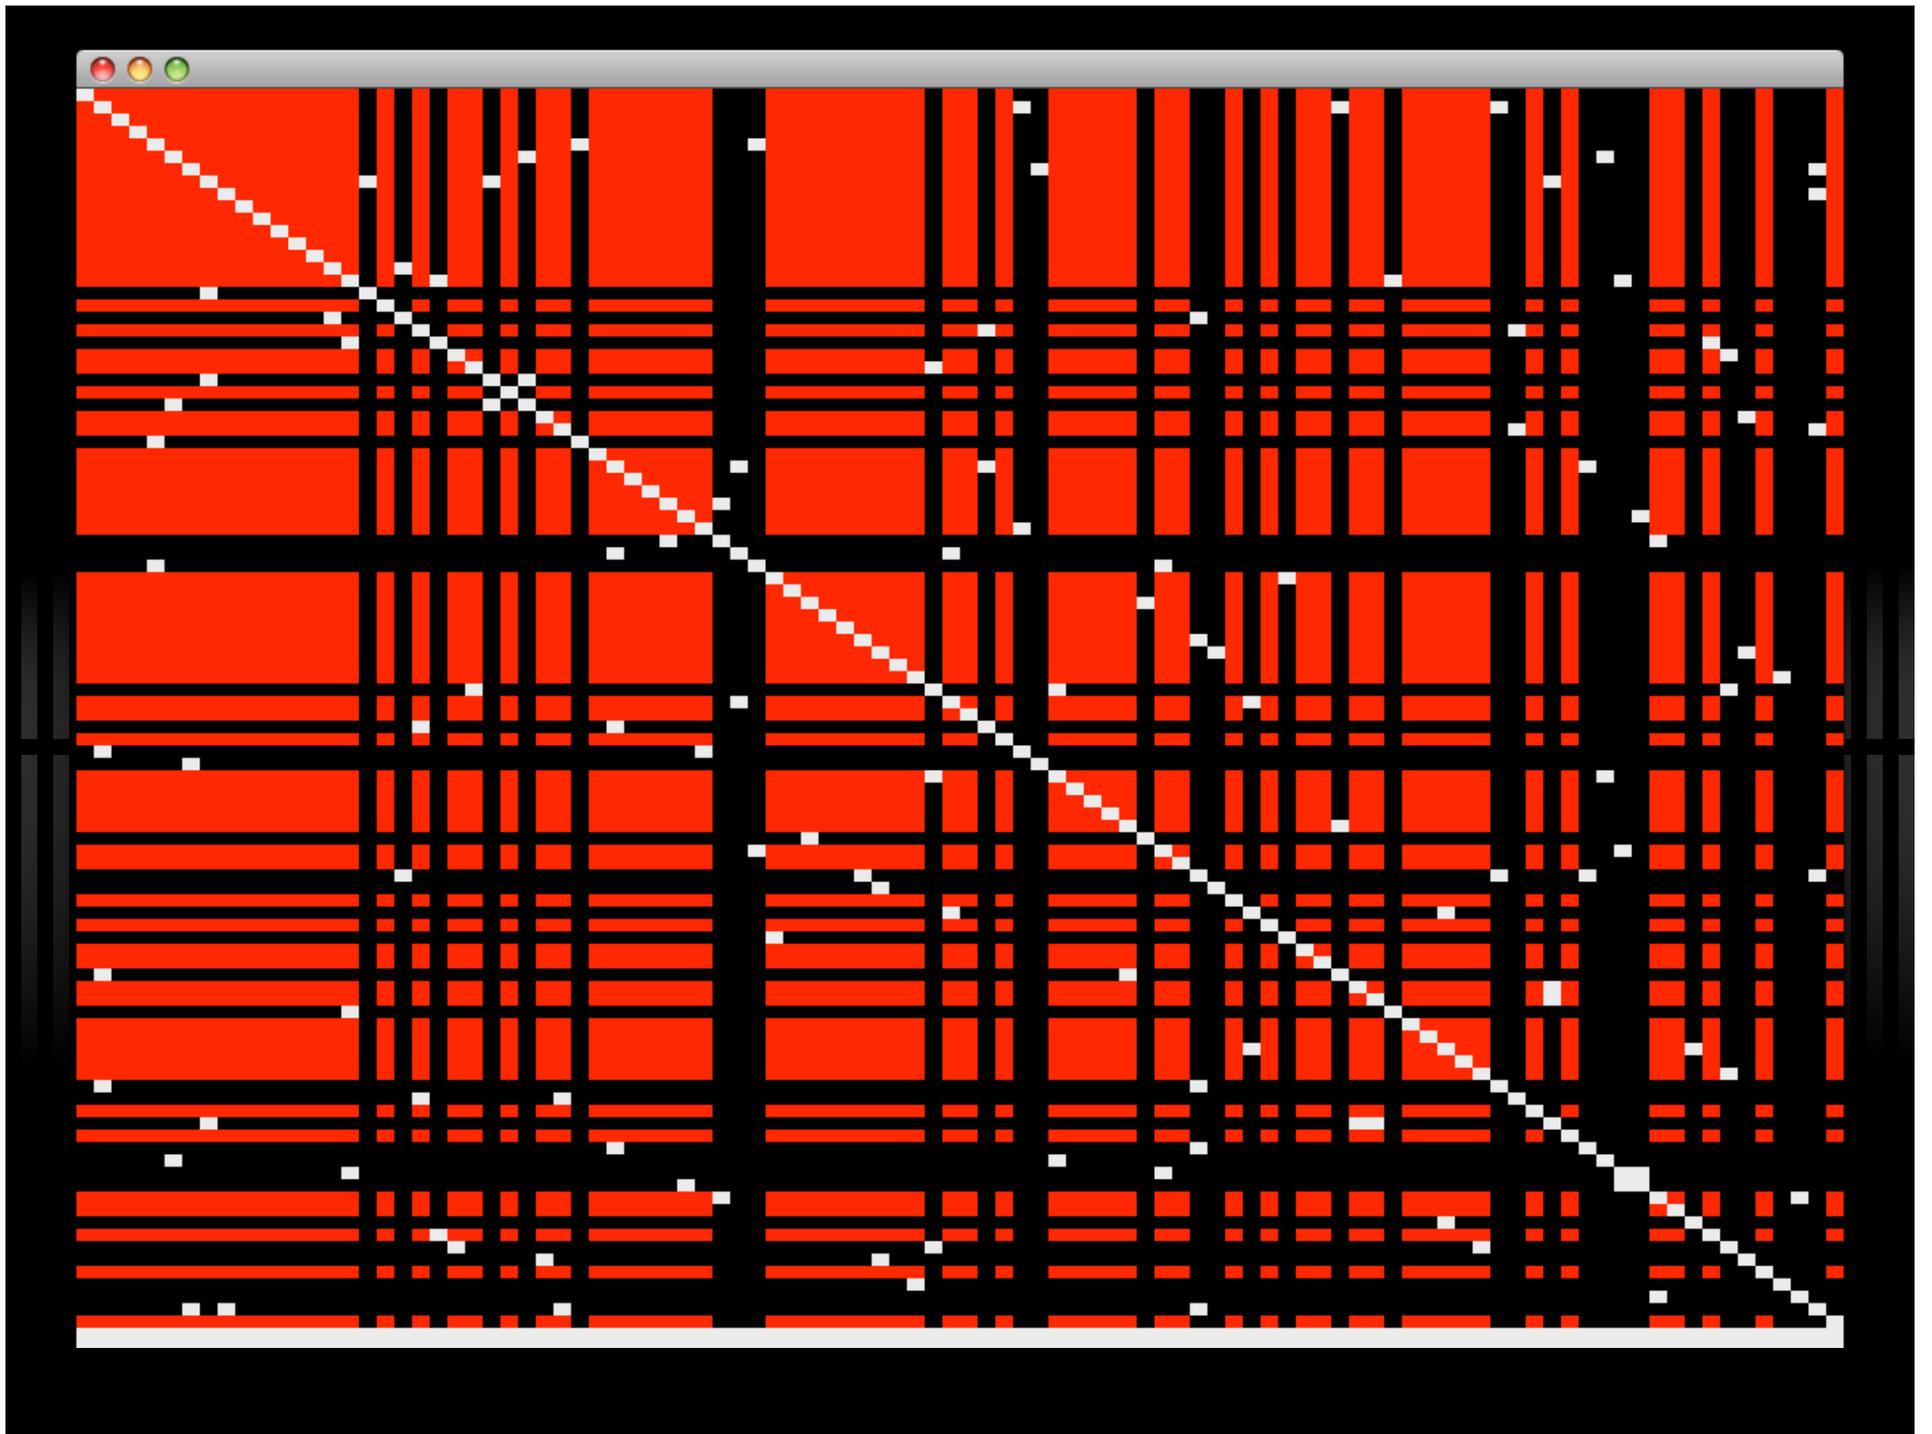

Communicates bounds

At staggered time intervals

Note: we *must* take wide intervals, otherwise the overhead will dominate over any gains

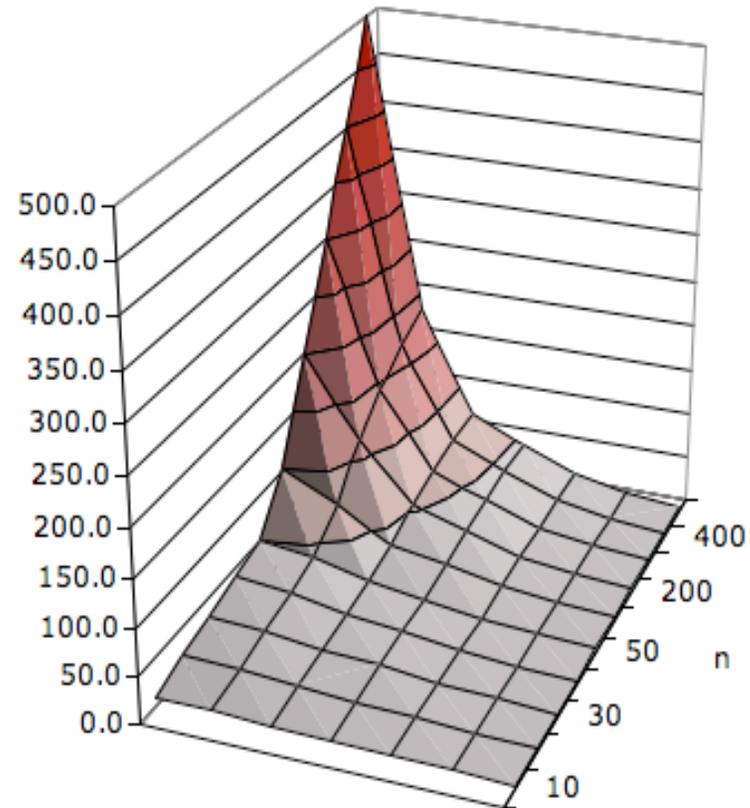

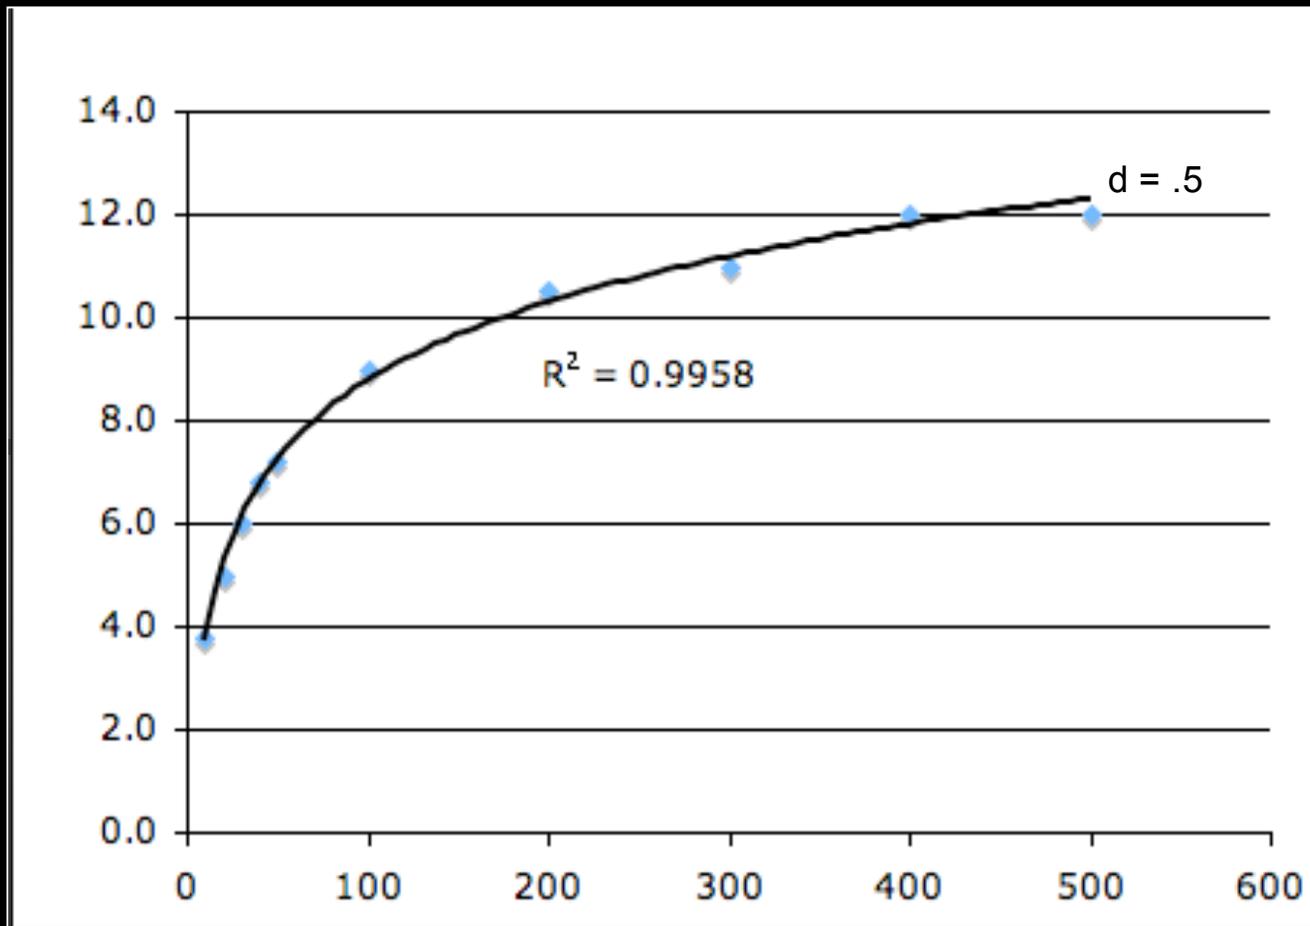

Run Time

- ✓ *A naïve approach will search all 2^n permutations*
- ✓ *But remember, we never search larger graphs than we need to...*
- ✓ *Must be a function of $M(x)$*
- ✓ *$M(x)$ appears to grow as $\mathcal{O}(\log[n])$ for wide density range*

Maximum Clique as Function of Density and Data Size

Maximum Clique Vs Number of Vertices

Note: via our probabilistic method of construction, a graph of n vertices will have as its expected number of edges:

$$E = d(n^2 - n)/2$$

Where d is the density of the graph

Binomial Coefficients

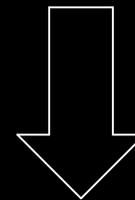

✓ Notice that $2^n = \sum_{i=0}^n \binom{n}{i}$

✓ Which we can cut off early...

M(n)

$$\sum_{i=3}^n i \binom{n}{i}$$

				1													
				1	1												
				1	2	1											
				1	3	3	1										
				1	4	6	4	1									
				1	5	10	10	5	1								
				1	6	15	20	15	6	1							
				1	7	21	35	35	21	7	1						
				1	8	28	56	70	56	28	8	1					
				1	9	36	84	126	126	84	36	9	1				
				1	10	45	120	210	252	210	45	10	1				
				1	11	55	165	330	462	462	330	165	55	11	1		
				1	12	66	220	495	792	924	924	792	495	220	66	12	1
				1	13	78	286	715	1287	1716	1716	1287	715	286	78	13	1
				1	14	91	364	1001	2002	3003	3003	2002	1001	364	91	14	1
				1	15	105	455	1365	3003	5005	5005	3003	1365	455	105	15	1
				1	16	120	560	1820	4368	8008	8008	4368	1820	560	120	16	1

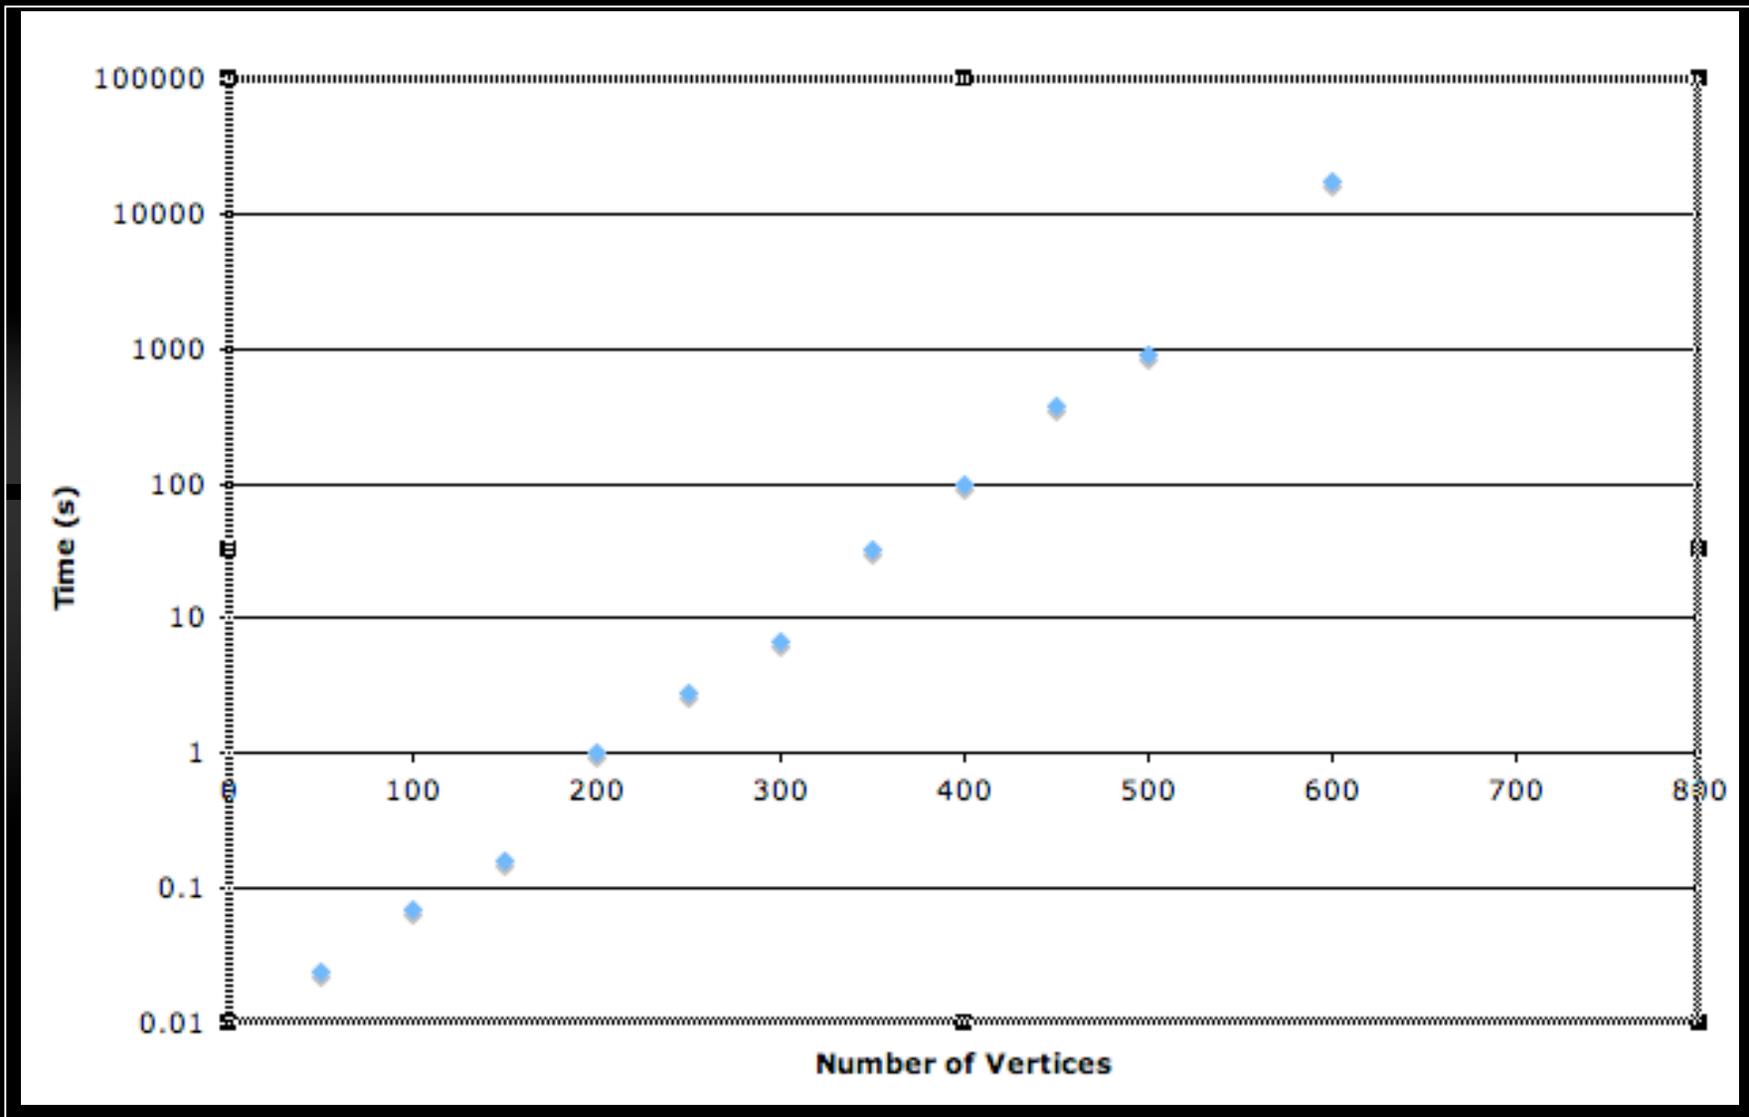

Closing the Gap

- ✓ We want to kill off all but the last term *without* imposing a strict identity on $M(n)$
- ✓ We must guarantee increasing slope over some region and verify true for the bottom end

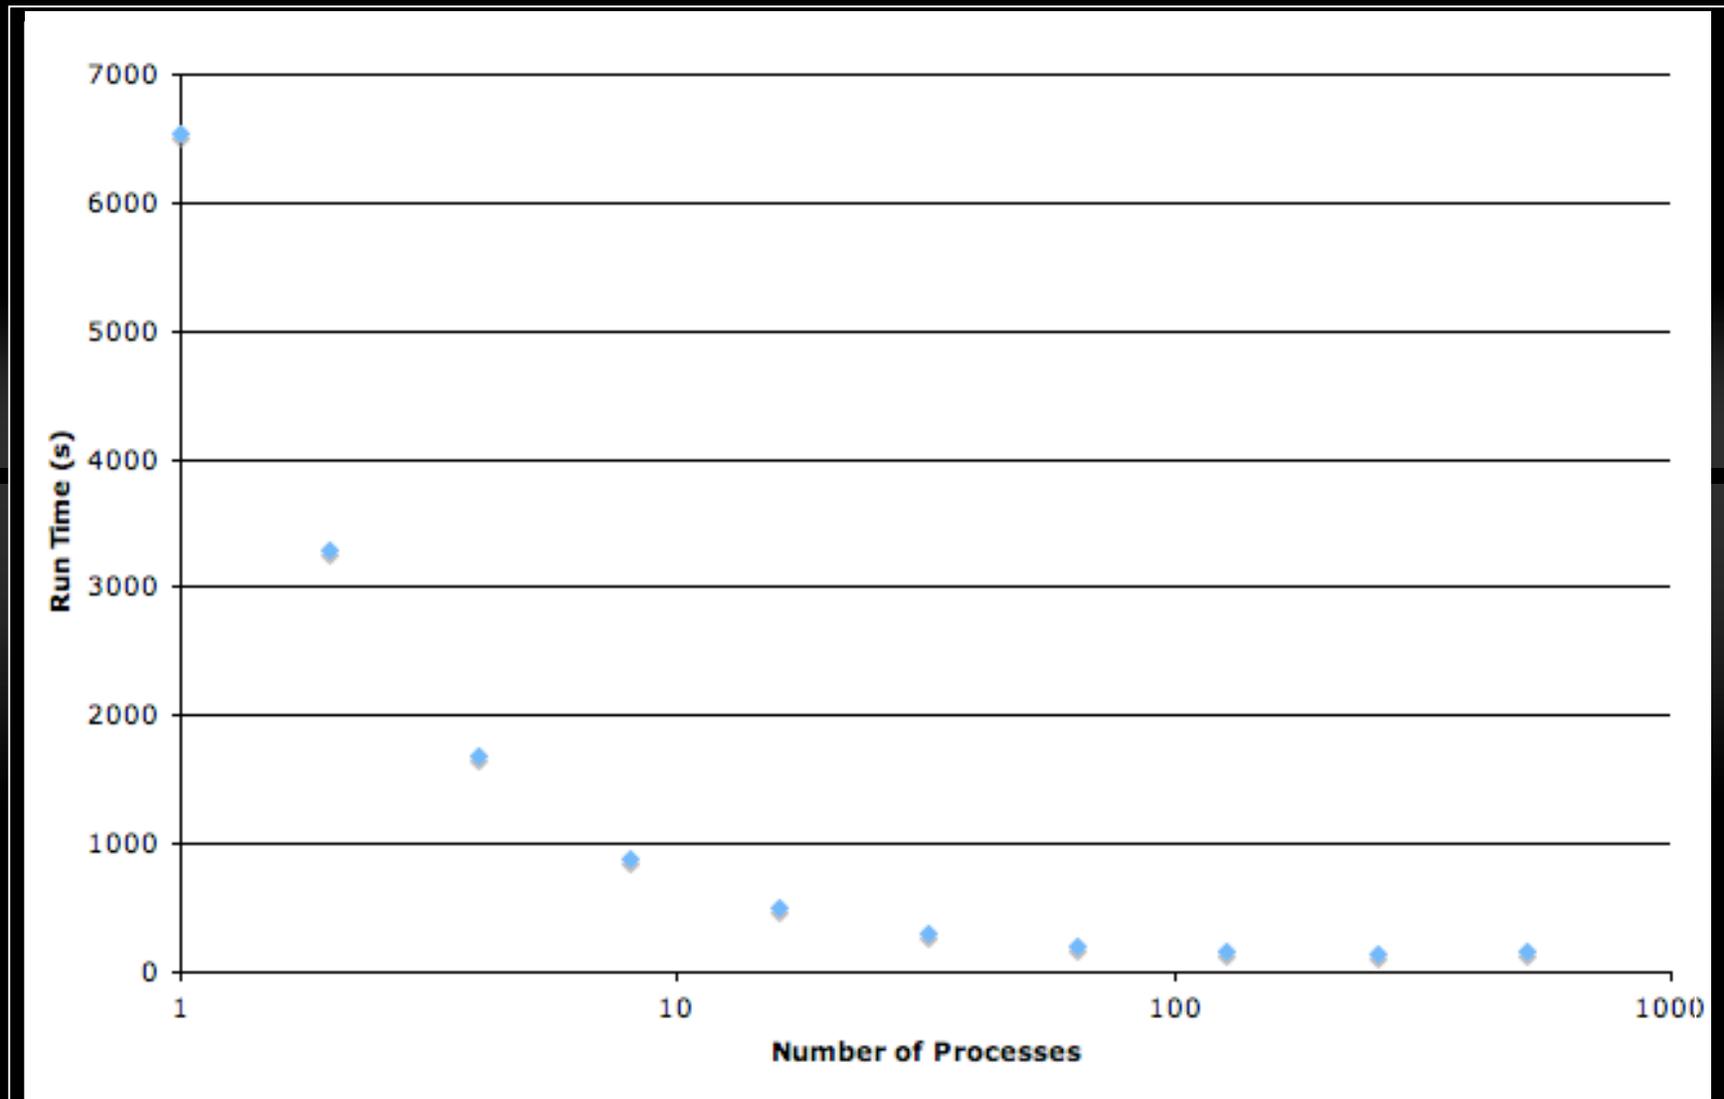

- ✓ We want some domain of $x, \geq 0$ such that $\lim_{n \rightarrow \infty} \partial_i^2 \binom{n}{i} \Big|_{i = \frac{xn}{2x+1}} = \infty$

Run Time Vs. Data Size

Run Time Vs. Number of Processes

Approximate Solution

- ✓ For *any* graph size the algorithm *will* find good approximation quickly

(even though it will continue searching for exponential time to *ensure* global quality)

But now for the catch...

- ✓ This is merely an artifact of the homogeneity implicit in our method of construction of the graph
- ✓ In general this will not work
- ✓ But we can recover this characteristic if we order nodes based on edge density
