

CSE 421/521 - Operating Systems  
Fall 2011

LECTURE - XIII

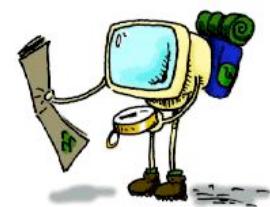

## MAIN MEMORY MANAGEMENT - II

Tevfik Koşar

University at Buffalo  
October 13<sup>th</sup>, 2011

## Roadmap

- Main Memory Management
  - Fragmentation
  - Address Binding
  - HW Address Protection
  - Paging

## Dynamic Storage-Allocation Problem

How to satisfy a request of size  $n$  from a list of free holes

- **First-fit**: Allocate the *first* hole that is big enough
- **Best-fit**: Allocate the *smallest* hole that is big enough; must search entire list, unless ordered by size. Produces the smallest leftover hole.
- **Worst-fit**: Allocate the *largest* hole; must also search entire list. Produces the largest leftover hole.

First-fit is faster.

Best-fit is better in terms of storage utilization.

Worst-fit may lead less fragmentation.

30

## Fragmentation

- **External Fragmentation** - total memory space exists to satisfy a request, but it is not contiguous (in average ~50% lost)
- **Internal Fragmentation** - allocated memory may be slightly larger than requested memory; this size difference is memory internal to a partition, but not being used
- Reduce external fragmentation by **compaction**
  - Shuffle memory contents to place all free memory together in one large block
  - Compaction is possible *only* if relocation is dynamic, and is done at execution time

32

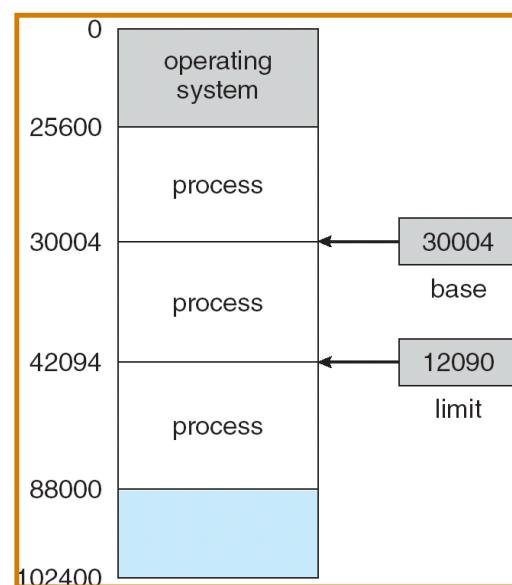

## Address Binding

- Addresses in a source program are generally **symbolic**
  - eg. int count;
- A compiler **binds** these symbolic addresses to **relocatable** addresses
  - eg. 100 bytes from the beginning of this module
- The linkage editor or loader will in turn bind the relocatable addresses to **absolute** addresses
  - eg. 74014
- Each binding is **mapping** from one address space to another

5

## Logical Address Space

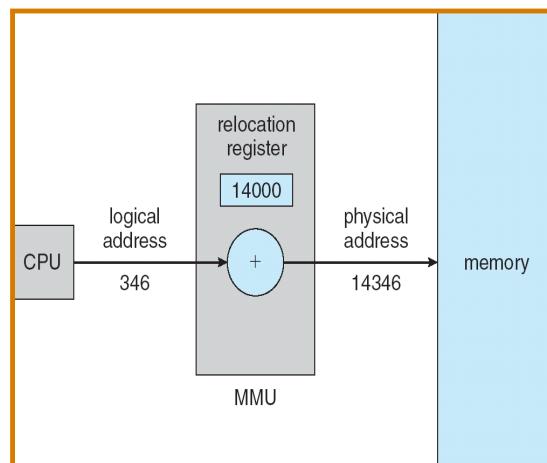

- Each process has a separate memory space
- Two registers provide address protection between processes:
  - **Base register:** smallest legal address space
  - **Limit register:** size of the legal range

6

## Memory-Management Unit (MMU)

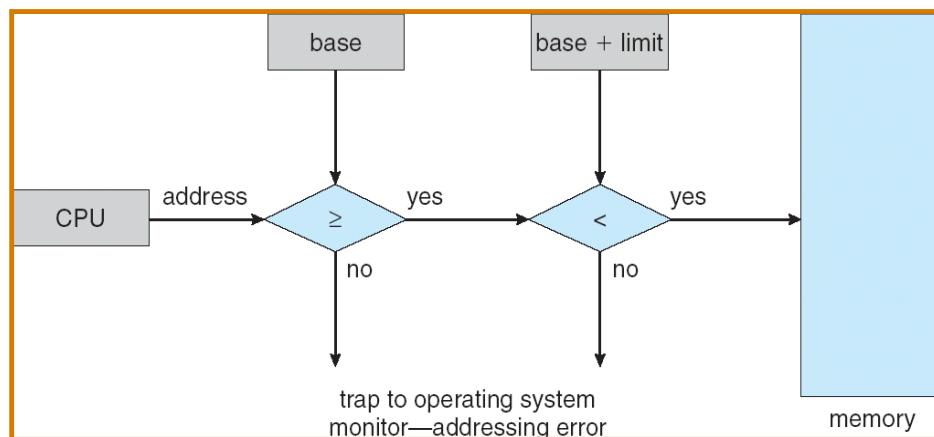

- Hardware device that maps logical to physical address
- In MMU scheme, the value in the **relocation register** (base register) is added to every address generated by a user process at the time it is sent to memory
- The **user program** deals with *logical* addresses; it **never sees the real physical addresses**

7

## HW Address Protection

- CPU hardware compares every address generated in user mode with the registers
- Any attempt to access other processes' memory will be trapped and cause a **fatal error**

8

## Paging - noncontiguous

- Physical address space of a process can be noncontiguous
- Divide physical memory into fixed-sized blocks called **frames** (size is power of 2, between 512 bytes and 16 megabytes)
- Divide logical memory into blocks of same size called **pages**.
- Keep track of all free frames
- To run a program of size  $n$  pages, need to find  $n$  free frames and load program
- Set up a page table to translate logical to physical addresses
- **Internal fragmentation**

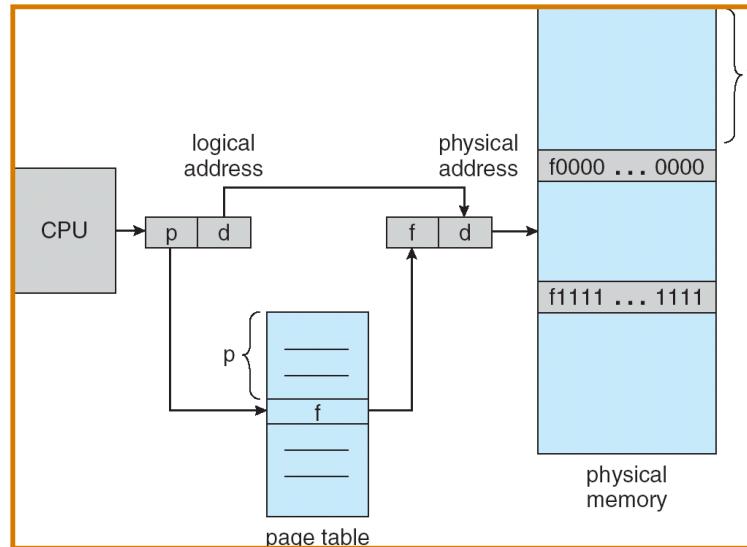

37

## Address Translation Scheme

- Address generated by CPU is divided into:
  - **Page number (p)** - used as an index into a *page table* which contains base address of each page in physical memory
  - **Page offset (d)** - combined with base address to define the physical memory address that is sent to the memory unit

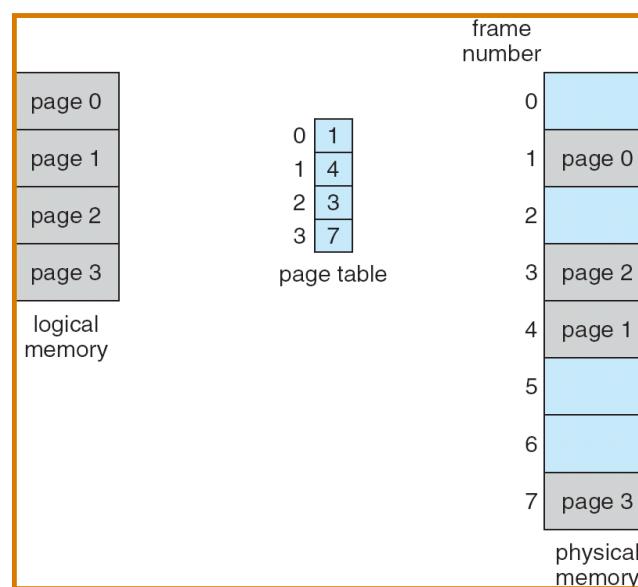

38

## Address Translation Architecture

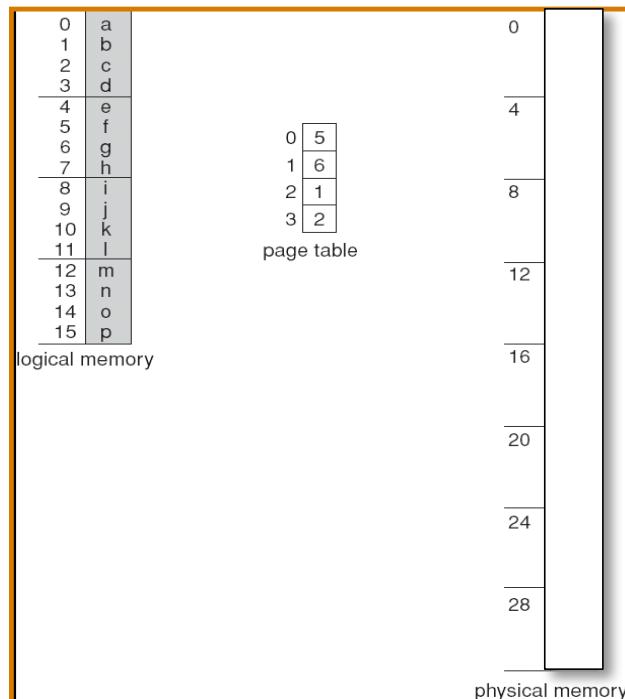

39

## Paging Example

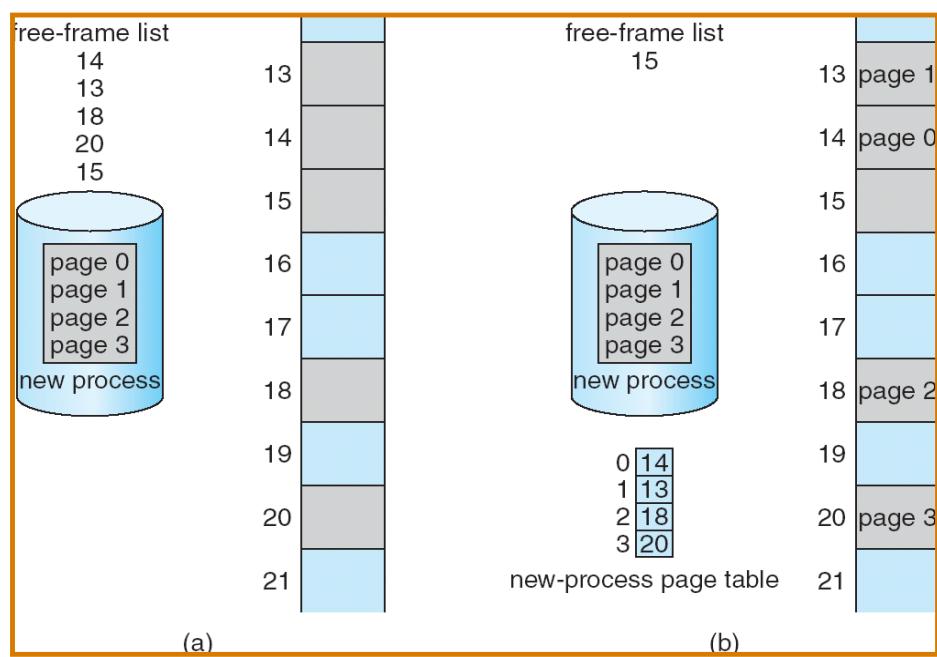

40

## Paging Example

41

## Free Frames

42

## Shared Pages

- **Shared code**

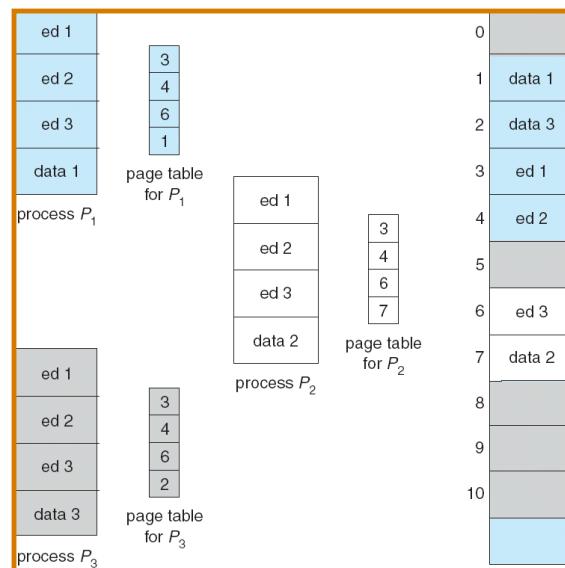

- One copy of read-only (reentrant) code shared among processes (i.e., text editors, compilers, window systems).
- Shared code must appear in same location in the logical address space of all processes

- **Private code and data**

- Each process keeps a separate copy of the code and data
- The pages for the private code and data can appear anywhere in the logical address space

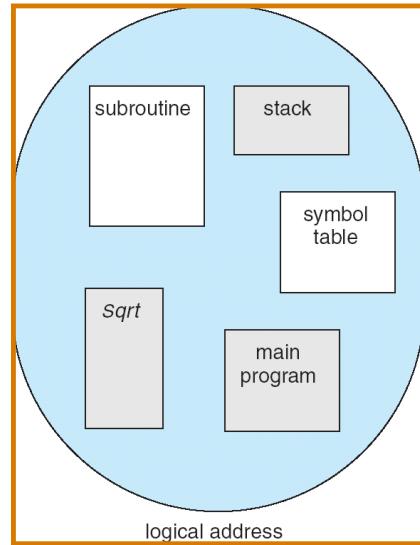

22

## Shared Pages Example

23

## User's View of a Program

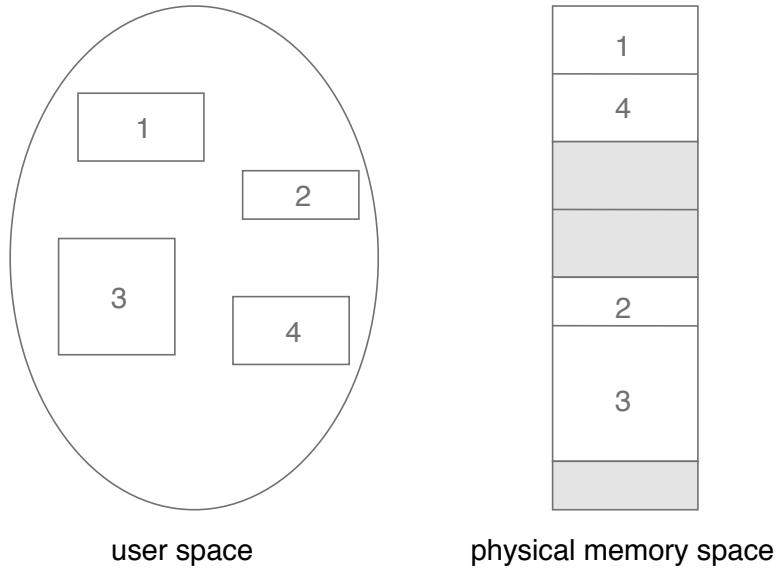

24

## Segmentation

- Memory-management scheme that supports user view of memory
- A program is a collection of segments. A segment is a logical unit such as:
  - main program,
  - procedure,
  - function,
  - method,
  - object,
  - local variables, global variables,
  - common block,
  - stack,
  - symbol table, arrays

25

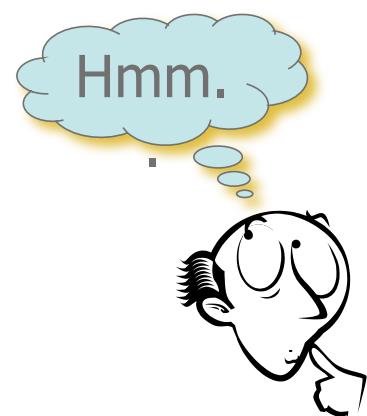

## Logical View of Segmentation

26

## Summary

- Main Memory Management
  - Fragmentation
  - Address Binding
  - HW Address Protection
  - Paging
- Next Lecture: Midterm Review
