

Variables, Strings, and Loops

CSE 220: Systems Programming

Ethan Blanton

Department of Computer Science and Engineering

University at Buffalo

Types

C is a **typed language**.

Every **variable** has a type, and is **declared**.

Every **value assigned to a variable** must match that type.

The compiler will automatically convert between some types.¹

Valid:

```
int x = 0;
float y = 0;
x = 37;
y = x;
```

Invalid:

```
int x = 0;
x = "Hello, world!";
```

¹DMR says “C is strongly typed, but weakly enforced.”

Some Types

There are **many types**; for now, consider:

- **int**: Integers of a convenient size for the computer (32-bit for us)
- **char**: Characters (typically 8-bit integers)
- **double**: Double-precision floating-point numbers

There are also **array types**.

Array types are declared with square brackets: []:

- **char** a[]: An array of characters. Often used for **C strings**.
- **int** scores[200]: An array of **exactly 200** integers.

Time Management

The **Carnegie Rule**: 2-3 hours of work **outside class** per credit

That's why 12 credits is **full time**!

Plan accordingly:

- **Schedule** ~1.5 hours per lecture in a block
 - Too long: hard to focus
 - Too short: lost time to overhead
- Work **every day**, not all at once
- Schedule the other 0.5–1.5 hours **as needed**

Administrivia

Have you done your assigned reading?

Is your VM working?

Did you compile and run Hello World?

Remember that many of you are new to the command prompt!
Check the Piazza post on this.

Read [everything](#) for all assignments and labs.

Check Piazza frequently.

There will be a [lecture quiz](#) for this lecture (after we finish it).

Declaring Variables

Variables are **declared** by **stating their type and name**.

```
int x;           /* x is an integer */  
double d;       /* d is a floating-point double */
```

Variables retain their type **while they are in scope**.

Various modifiers can be applied to variables.

In particular, **const** declares the variable is a constant.

Scope

Variables in C have **scope**.

A variable cannot be used **out of scope**.

Variables declared **outside of any block** ({}):

- are normally **global**: they can be accessed by **any code**
- are **file-local** with the modifier **static**: they can be accessed by any code **in this file**

Variables declared **in a block**:

- Come into scope **where declared** ¶
- are valid until the scope's **}** or end-of-file

Arrays

C arrays are **a series of contiguous memory locations**.

(This will become important later.)

Arrays are declared with `[]`. The size is between `[]`.

Arrays can have three “sizes”, depending on what’s in the `[]`:

- **Unknown size**: Nothing is specified
- **Constant size**: A constant expression is specified
- **Variable size**: A run-time computed expression is specified

Array Sizes

Array sizes specify **how many elements are in the array**.

```
int x[32];  
int matrix[32][16];
```

C **does not remember** the array's size. ¹

This means that **illegal accesses aren't caught**.²

```
int x[4];  
x[10234] = 0;           /* Whoops. */
```

²If you're lucky, you might get a warning about uninitialized access.

Static Initializers

An array can be initialized **all at once** at declaration.

```
int array[10] = { 0, 3, 5, 0, 0,  
                1, 0, 0, 2, 0 };
```

This is called a **static initializer**.

Static initializers **can be used only at declaration**.

```
int array[3];
```

```
array = { 1, 3, 5 };    /* syntax error */
```

C Strings

C strings are just arrays.

Strings, like arrays, are not associated with a length.

(You have to count the characters to know how long they are.) ¶

A C string consists of:

- the characters in the string, followed by
- a zero byte (the ASCII NUL character) (NUL terminator).

The zero byte is idiomatically written `'\0'`.

Quoted Strings

Quoted strings automatically build such arrays.

```
char str[] = "Hello";  
char str[] = { 'H', 'e', 'l', 'l', 'o', '\0' };
```

A quoted string may be assigned to an **array only at declaration**.

After declaration, quoted strings must be **copied into** arrays:

```
char str[32];  
  
strncpy(str, 32, "Hello");    /* See man 3 strncpy */
```

String Functions

There are **many string functions** in the C library.

Most of them are defined in `<string.h>`.

Some useful examples:

- `strlen()`: Compute the length of a string by counting bytes
- `strncpy()`: Copy a string until its NUL character
- `strncat()`: Concatenate one string to another
- `strstr()`: Search for one string inside another

Strings as Pointers

The idiomatic string type is `char *`.

Arrays and pointers are **closely related**, we'll discuss this later.

```
char *str = "Hello, CSE 220";
```

```
char array[] = "Another string";
```

```
char *otherstr = array;
```

Character Constants

C strings can be in many encodings, but C code is in ASCII. ¶

ASCII contains Latin characters, numbers, and punctuation.

An ASCII character can be **converted to an integer** with `' '`.

```
char c = 'A';           /* 65 */
int i = 'B';           /* 66 */
```

Each byte of a string can be assigned in this fashion.

```
char str[] = "emacs";
/* Give it the respect it deserves */
str[0] = 'E';
```

The for Loop

The C for loop is its **most versatile** loop.

It allows looping over **almost anything**.

```
for (initialization; condition; increment) {  
    body;  
}
```

It translates to a more traditional while loop (with caveats):

```
initialization;  
while (condition) {  
    body;  
    increment;  
}
```

Looping over Arrays

A common use of the `for` loop is looping over arrays:

```
int array[ARRAYSZ];

for (int i = 0; i < ARRAYSZ; i++) {
    /* Use array[i] */
}
```

Remember that you must somehow know the size of the array.

Looping over Strings

It is **idiomatic** to loop over strings:

```
for (int i = 0; str[i] != '\0'; i++) {  
    /* use str[i] */  
}
```

Note that the string length is **never directly computed!**

Strings, Arrays, and Loop Example

We will develop `strlen()` together.

Summary

- C is a **typed language**
- **Every variable** has a type
- Variable values must **match** the type
- Variables have **scope**, and cannot be used outside that scope
- Arrays are **contiguous memory locations**
- Array syntax uses `[]`
- C strings are arrays of characters
- Every C string is **terminated with a zero byte**
- For loop syntax
- For loops are very flexible

Next Time ...

- Boolean values
- Conditional statements
- Control flow
