### Nonparametric Methods

Jason Corso

SUNY at Buffalo

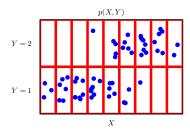

#### Nonparametric Methods Overview

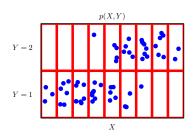

- Previously, we've assumed that the forms of the underlying densities were of some particular known parametric form.
- But, what if this is not the case?
- Indeed, for most real-world pattern recognition scenarios this assumption is suspect.
- For example, most real-world entities have multimodal distributions whereas classical parametric densities are primarily unimodal.

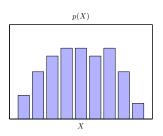

#### Nonparametric Methods Overview

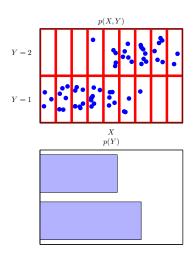

- Previously, we've assumed that the forms of the underlying densities were of some particular known parametric form.
- But, what if this is not the case?
- Indeed, for most real-world pattern recognition scenarios this assumption is suspect.
- For example, most real-world entities have multimodal distributions whereas classical parametric densities are primarily unimodal.
- We will examine nonparametric procedures that can be used with arbitrary distributions and without the assumption that the underlying form of the densities are known.
  - Histograms.
  - Kernel Density Estimation / Parzen Windows.
  - k-Nearest Neighbor Density Estimation.
  - Real Example in Figure-Ground Segmentation

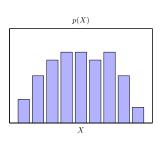

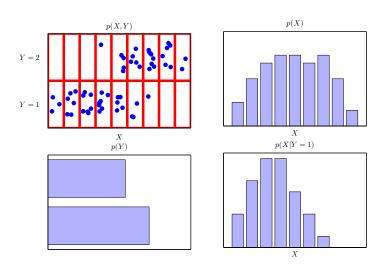

• Consider a single continuous variable x and let's say we have a set  $\mathcal{D}$  of N of them  $\{x_1, \ldots, x_N\}$ . Our goal is to model p(x) from  $\mathcal{D}$ .

- Consider a single continuous variable x and let's say we have a set  $\mathcal{D}$  of N of them  $\{x_1, \ldots, x_N\}$ . Our goal is to model p(x) from  $\mathcal{D}$ .
- Standard histograms simply partition x into distinct bins of width  $\Delta_i$  and then count the number  $n_i$  of observations x falling into bin i.

- Consider a single continuous variable x and let's say we have a set  $\mathcal{D}$  of N of them  $\{x_1, \ldots, x_N\}$ . Our goal is to model p(x) from  $\mathcal{D}$ .
- Standard histograms simply partition x into distinct bins of width  $\Delta_i$  and then count the number  $n_i$  of observations x falling into bin i.
- ullet To turn this count into a normalized probability density, we simply divide by the total number of observations N and by the width  $\Delta_i$  of the bins.
- This gives us:

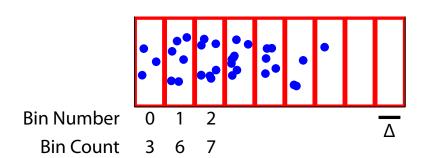

$$p_i = \frac{n_i}{N\Delta_i} \tag{1}$$

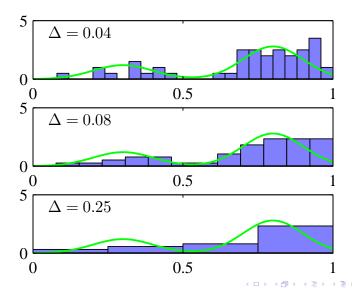

- Consider a single continuous variable x and let's say we have a set  $\mathcal{D}$  of N of them  $\{x_1, \ldots, x_N\}$ . Our goal is to model p(x) from  $\mathcal{D}$ .
- Standard histograms simply partition x into distinct bins of width  $\Delta_i$  and then count the number  $n_i$  of observations x falling into bin i.
- ullet To turn this count into a normalized probability density, we simply divide by the total number of observations N and by the width  $\Delta_i$  of the bins.
- This gives us:

$$p_i = \frac{n_i}{N\Delta_i} \tag{1}$$

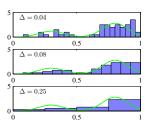

• Hence the model for the density p(x) is constant over the width of each bin. (And often the bins are chosen to have the same width  $\Delta_i = \Delta$ .)

 The green curve is the underlying true density from which the samples were drawn. It is a mixture of two Gaussians.

- The green curve is the underlying true density from which the samples were drawn. It is a mixture of two Gaussians.
- When  $\Delta$  is very small (top), the resulting density is quite spiky and hallucinates a lot of structure not present in p(x).

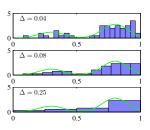

- The green curve is the underlying true density from which the samples were drawn. It is a mixture of two Gaussians.
- When  $\Delta$  is very small (top), the resulting density is quite spiky and hallucinates a lot of structure not present in p(x).

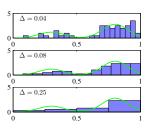

• When  $\Delta$  is very big (bottom), the resulting density is quite smooth and consequently fails to capture the bimodality of p(x).

- The green curve is the underlying true density from which the samples were drawn. It is a mixture of two Gaussians.
- When  $\Delta$  is very small (top), the resulting density is quite spiky and hallucinates a lot of structure not present in p(x).

- When  $\Delta$  is very big (bottom), the resulting density is quite smooth and consequently fails to capture the bimodality of p(x).
- It appears that the *best results* are obtained for some intermediate value of  $\Delta$ , which is given in the middle figure.

- The green curve is the underlying true density from which the samples were drawn. It is a mixture of two Gaussians.
- When  $\Delta$  is very small (top), the resulting density is quite spiky and hallucinates a lot of structure not present in p(x).

- When  $\Delta$  is very big (bottom), the resulting density is quite smooth and consequently fails to capture the bimodality of p(x).
- It appears that the *best results* are obtained for some intermediate value of  $\Delta$ , which is given in the middle figure.
- In principle, a histogram density model is also dependent on the choice of the edge location of each bin.

#### **Analyzing the Histogram Density**

• What are the advantages and disadvantages of the histogram density estimator?

#### **Analyzing the Histogram Density**

- What are the advantages and disadvantages of the histogram density estimator?
- Advantages:
  - Simple to evaluate and simple to use.
  - ullet One can throw away  ${\mathcal D}$  once the histogram is computed.
  - Can be computed sequentially if data continues to come in.

#### **Analyzing the Histogram Density**

- What are the advantages and disadvantages of the histogram density estimator?
- Advantages:
  - Simple to evaluate and simple to use.
  - ullet One can throw away  ${\mathcal D}$  once the histogram is computed.
  - Can be computed sequentially if data continues to come in.
- Disadvantages:
  - The estimated density has discontinuities due to the bin edges rather than any property of the underlying density.
  - Scales poorly (curse of dimensionality): we would have  ${\cal M}^D$  bins if we divided each variable in a D-dimensional space into  ${\cal M}$  bins.

# What can we learn from Histogram Density Estimation?

- Lesson 1: To estimate the probability density at a particular location, we should consider the data points that lie within some local neighborhood of that point.
  - This requires we define some distance measure.
  - There is a natural smoothness parameter describing the spatial extent of the regions (this was the bin width for the histograms).

# What can we learn from Histogram Density Estimation?

- Lesson 1: To estimate the probability density at a particular location, we should consider the data points that lie within some local neighborhood of that point.
  - This requires we define some distance measure.
  - There is a natural smoothness parameter describing the spatial extent of the regions (this was the bin width for the histograms).
- Lesson 2: The value of the smoothing parameter should neither be too large or too small in order to obtain good results.

## What can we learn from Histogram Density Estimation?

- Lesson 1: To estimate the probability density at a particular location, we should consider the data points that lie within some local neighborhood of that point.
  - This requires we define some distance measure.
  - There is a natural smoothness parameter describing the spatial extent of the regions (this was the bin width for the histograms).
- Lesson 2: The value of the smoothing parameter should neither be too large or too small in order to obtain good results.
- With these two lessons in mind, we proceed to kernel density estimation and nearest neighbor density estimation, two closely related methods for density estimation.

- ullet Consider again samples  ${f x}$  from underlying density  $p({f x})$ .
- Let  $\mathcal{R}$  denote a small region containing  $\mathbf{x}$ .

- Consider again samples x from underlying density p(x).
- Let  $\mathcal R$  denote a small region containing  $\mathbf x$ .
- ullet The probability mass associated with  ${\mathcal R}$  is given by

$$P = \int_{\mathcal{R}} p(\mathbf{x}') d\mathbf{x}' \tag{2}$$

- Consider again samples x from underlying density p(x).
- Let  $\mathcal R$  denote a small region containing  $\mathbf x$ .
- ullet The probability mass associated with  ${\cal R}$  is given by

$$P = \int_{\mathcal{R}} p(\mathbf{x}') d\mathbf{x}' \tag{2}$$

- Suppose we have n samples  $\mathbf{x} \in \mathcal{D}$ . The probability of each sample falling into  $\mathcal{R}$  is P.
- How will the total number of k points falling into  $\mathcal R$  be distributed?

- Consider again samples x from underlying density p(x).
- Let  $\mathcal{R}$  denote a small region containing  $\mathbf{x}$ .
- ullet The probability mass associated with  ${\cal R}$  is given by

$$P = \int_{\mathcal{R}} p(\mathbf{x}') d\mathbf{x}' \tag{2}$$

- Suppose we have n samples  $\mathbf{x} \in \mathcal{D}$ . The probability of each sample falling into  $\mathcal{R}$  is P.
- How will the total number of k points falling into  $\mathcal R$  be distributed?
- This will be a binomial distribution:

$$P_k = \binom{n}{k} P^k (1 - P)^{n-k} \tag{3}$$

ullet The expected value for k is thus

$$\mathcal{E}[k] = nP \tag{4}$$

• The expected value for k is thus

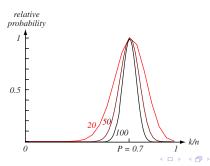

$$\mathcal{E}[k] = nP \tag{4}$$

• The binomial for k peaks very sharply about the mean. So, we expect k/n to be a very good estimate for the probability P (and thus for the space-averaged density).

• The expected value for k is thus

$$\mathcal{E}[k] = nP \tag{4}$$

- The binomial for k peaks very sharply about the mean. So, we expect k/n to be a very good estimate for the probability P (and thus for the space-averaged density).
- ullet This estimate is increasingly accurate as n increases.

• Assuming continuous  $p(\mathbf{x})$  and that  $\mathcal{R}$  is so small that  $p(\mathbf{x})$  does not appreciably vary within it, we can write:

$$\int_{\mathcal{R}} p(\mathbf{x}') d\mathbf{x}' \simeq p(\mathbf{x}) V \tag{5}$$

where x is a point within  $\mathcal{R}$  and V is the volume enclosed by  $\mathcal{R}$ .

• Assuming continuous  $p(\mathbf{x})$  and that  $\mathcal{R}$  is so small that  $p(\mathbf{x})$  does not appreciably vary within it, we can write:

$$\int_{\mathcal{R}} p(\mathbf{x}') d\mathbf{x}' \simeq p(\mathbf{x}) V \tag{5}$$

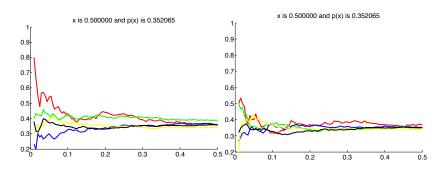

where x is a point within  $\mathcal{R}$  and V is the volume enclosed by  $\mathcal{R}$ .

• After some rearranging, we get the following estimate for  $p(\mathbf{x})$ 

$$p(\mathbf{x}) \simeq \frac{k}{nV} \tag{6}$$

#### **Example**

- Simulated an example of example the density at 0.5 for an underlying zero-mean, unit variance Gaussian.
- Varied the volume used to estimate the density.
- Red=1000, Green=2000, Blue=3000, Yellow=4000, Black=5000.

#### **Practical Concerns**

- The validity of our estimate depends on two contradictory assumptions:
  - ① The region  $\mathcal{R}$  must be sufficiently small the the density is approximately constant over the region.
  - ② The region  $\mathcal{R}$  must be sufficiently large that the number k of points falling inside it is sufficient to yield a sharply peaked binomial.

#### **Practical Concerns**

- The validity of our estimate depends on two contradictory assumptions:
  - **1** The region  $\mathcal{R}$  must be sufficiently small the the density is approximately constant over the region.
  - ② The region  $\mathcal{R}$  must be sufficiently large that the number k of points falling inside it is sufficient to yield a sharply peaked binomial.
- Another way of looking it is to fix the volume V and increase the number of training samples. Then, the ratio k/n will converge as desired. But, this will only yield an estimate of the space-averaged density (P/V).

### **Practical Concerns**

- The validity of our estimate depends on two contradictory assumptions:
  - ① The region  $\mathcal{R}$  must be sufficiently small the the density is approximately constant over the region.
  - ② The region  $\mathcal{R}$  must be sufficiently large that the number k of points falling inside it is sufficient to yield a sharply peaked binomial.
- Another way of looking it is to fix the volume V and increase the number of training samples. Then, the ratio k/n will converge as desired. But, this will only yield an estimate of the space-averaged density (P/V).
- We want  $p(\mathbf{x})$ , so we need to let V approach 0. However, with a fixed n,  $\mathcal{R}$  will become so small, that no points will fall into it and our estimate would be useless:  $p(\mathbf{x}) \simeq 0$ .

### **Practical Concerns**

  - ① The region  $\mathcal{R}$  must be sufficiently small the the density is approximately constant over the region.
  - ② The region  $\mathcal{R}$  must be sufficiently large that the number k of points falling inside it is sufficient to yield a sharply peaked binomial.
- Another way of looking it is to fix the volume V and increase the number of training samples. Then, the ratio k/n will converge as desired. But, this will only yield an estimate of the space-averaged density (P/V).
- We want  $p(\mathbf{x})$ , so we need to let V approach 0. However, with a fixed n,  $\mathcal{R}$  will become so small, that no points will fall into it and our estimate would be useless:  $p(\mathbf{x}) \simeq 0$ .
- Note that in practice, we cannot let V to become arbitrarily small because the number of samples is always limited.

How can we skirt these limitations when an unlimited number of samples if available?

• To estimate the density at x, form a sequence of regions  $\mathcal{R}_1, \mathcal{R}_2, \dots$ containing x with the  $\mathcal{R}_1$  having 1 sample  $(n_1 = 1)$ ,  $\mathcal{R}_2$  having 2 samples  $(n_2 = 2)$  and so on.

How can we skirt these limitations when an unlimited number of samples if available?

- To estimate the density at x, form a sequence of regions  $\mathcal{R}_1, \mathcal{R}_2, \dots$ containing x with the  $\mathcal{R}_1$  having 1 sample  $(n_1 = 1)$ ,  $\mathcal{R}_2$  having 2 samples  $(n_2 = 2)$  and so on.
- Let  $V_n$  be the volume of  $\mathcal{R}_n$ ,  $k_n$  be the number of samples falling in  $\mathcal{R}_n$ , and  $p_n(\mathbf{x})$  be the *n*th estimate for  $p(\mathbf{x})$ :

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n} \tag{7}$$

How can we skirt these limitations when an unlimited number of samples if available?

- To estimate the density at x, form a sequence of regions  $\mathcal{R}_1, \mathcal{R}_2, \ldots$  containing x with the  $\mathcal{R}_1$  having 1 sample  $(n_1 = 1)$ ,  $\mathcal{R}_2$  having 2 samples  $(n_2 = 2)$  and so on.
- Let  $V_n$  be the volume of  $\mathcal{R}_n$ ,  $k_n$  be the number of samples falling in  $\mathcal{R}_n$ , and  $p_n(\mathbf{x})$  be the nth estimate for  $p(\mathbf{x})$ :

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n} \tag{7}$$

• If  $p_n(\mathbf{x})$  is to converge to  $p(\mathbf{x})$  we need the following three conditions

$$\lim_{n \to \infty} V_n = 0 \tag{8}$$

$$\lim_{n \to \infty} k_n = \infty \tag{9}$$

$$\lim_{n \to \infty} k_n / n = 0 \tag{10}$$

ullet  $\lim_{n o \infty} V_n = 0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .

- Kernel Density Estimation
- $\lim_{n\to\infty} V_n = 0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .
- $\lim_{n\to\infty} k_n = \infty$  basically ensures that the frequency ratio will converge to the probability P (the binomial will be sufficiently peaked).

- $\lim_{n\to\infty} V_n = 0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .
- $\lim_{n\to\infty} k_n = \infty$  basically ensures that the frequency ratio will converge to the probability P (the binomial will be sufficiently peaked).
- $\lim_{n\to\infty} k_n/n = 0$  is required for  $p_n(\mathbf{x})$  to converge at all. It also says that although a huge number of samples will fall within the region  $\mathcal{R}_n$ , they will form a negligibly small fraction of the total number of samples.

- $\lim_{n\to\infty} V_n = 0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .
- $\lim_{n\to\infty} k_n = \infty$  basically ensures that the frequency ratio will converge to the probability P (the binomial will be sufficiently peaked).
- $\lim_{n\to\infty} k_n/n = 0$  is required for  $p_n(\mathbf{x})$  to converge at all. It also says that although a huge number of samples will fall within the region  $\mathcal{R}_n$ , they will form a negligibly small fraction of the total number of samples.
- There are two common ways of obtaining regions that satisfy these conditions:

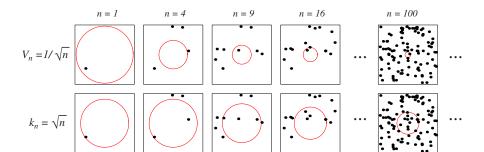

- $\lim_{n\to\infty} V_n = 0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .
- ullet  $\lim_{n o \infty} k_n = \infty$  basically ensures that the frequency ratio will converge to the probability P (the binomial will be sufficiently peaked).
- $\lim_{n\to\infty} k_n/n = 0$  is required for  $p_n(\mathbf{x})$  to converge at all. It also says that although a huge number of samples will fall within the region  $\mathcal{R}_n$ , they will form a negligibly small fraction of the total number of samples.
- There are two common ways of obtaining regions that satisfy these conditions:
  - Shrink an initial region by specifying the volume  $V_n$  as some function of n such as  $V_n = 1/\sqrt{n}$ . Then, we need to show that  $p_n(\mathbf{x})$  converges to  $p(\mathbf{x})$ . (This is like the Parzen window we'll talk about next.)

- $\lim_{n\to\infty} V_n = 0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .
- ullet  $\lim_{n o \infty} k_n = \infty$  basically ensures that the frequency ratio will converge to the probability P (the binomial will be sufficiently peaked).

  - 2 Specify  $k_n$  as some function of n such as  $k_n = \sqrt{n}$ . Then, we grow the volume  $V_n$  until it encloses  $k_n$  neighbors of x. (This is the k-nearest-neighbor).

- $\lim_{n\to\infty}V_n=0$  ensures that our space-averaged density will converge to  $p(\mathbf{x})$ .
- $\lim_{n\to\infty} k_n = \infty$  basically ensures that the frequency ratio will converge to the probability P (the binomial will be sufficiently peaked).
- $\lim_{n\to\infty} k_n/n=0$  is required for  $p_n(\mathbf{x})$  to converge at all. It also says that although a huge number of samples will fall within the region  $\mathcal{R}_n$ , they will form a negligibly small fraction of the total number of samples.
- There are two common ways of obtaining regions that satisfy these conditions:
  - ① Shrink an initial region by specifying the volume  $V_n$  as some function of n such as  $V_n = 1/\sqrt{n}$ . Then, we need to show that  $p_n(\mathbf{x})$  converges to  $p(\mathbf{x})$ . (This is like the Parzen window we'll talk about next.)
  - ② Specify  $k_n$  as some function of n such as  $k_n = \sqrt{n}$ . Then, we grow the volume  $V_n$  until it encloses  $k_n$  neighbors of  $\mathbf{x}$ . (This is the k-nearest-neighbor).

Both of these methods converge...

## **Parzen Windows**

• Let's temporarily assume the region  $\mathcal{R}$  is a d-dimensional hypercube with  $h_n$  being the length of an edge.

### **Parzen Windows**

- Let's temporarily assume the region  $\mathcal{R}$  is a d-dimensional hypercube with  $h_n$  being the length of an edge.
- The volume of the hypercube is given by

$$V_n = h_n^d (11)$$

#### **Parzen Windows**

- Let's temporarily assume the region  $\mathcal{R}$  is a d-dimensional hypercube with  $h_n$  being the length of an edge.
- The volume of the hypercube is given by

$$V_n = h_n^d (11)$$

- We can derive an analytic expression for  $k_n$ :
  - Define a windowing function:

$$\varphi(\mathbf{u}) = \begin{cases} 1 & |u_j| \le 1/2 & j = 1, \dots, d \\ 0 & \text{otherwise} \end{cases}$$
 (12)

- This windowing function  $\varphi$  defines a unit hypercube centered at the origin.
- Hence,  $\varphi((\mathbf{x} \mathbf{x}_i)/h_n)$  is equal to unity if  $\mathbf{x}_i$  falls within the hypercube of volume  $V_n$  centered at  $\mathbf{x}$ , and is zero otherwise.

• The number of samples in this hypercube is therefore given by

Parzen Windows

$$k_n = \sum_{i=1}^n \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) . \tag{13}$$

• The number of samples in this hypercube is therefore given by

$$k_n = \sum_{i=1}^n \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) . \tag{13}$$

• Substituting in equation (7),  $p_n(\mathbf{x}) = k_n/(nV_n)$  yields the estimate

$$p_n(\mathbf{x}) = \frac{1}{n} \sum_{i=1}^n \frac{1}{V_n} \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) . \tag{14}$$

• The number of samples in this hypercube is therefore given by

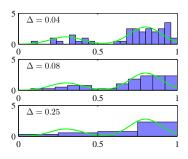

$$k_n = \sum_{i=1}^n \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) . \tag{13}$$

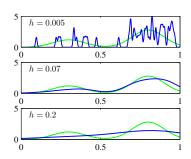

• Substituting in equation (7),  $p_n(\mathbf{x}) = k_n/(nV_n)$  yields the estimate

$$p_n(\mathbf{x}) = \frac{1}{n} \sum_{i=1}^n \frac{1}{V_n} \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) . \tag{14}$$

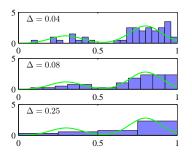

• Hence, the windowing function  $\varphi$ , in this context called a Parzen window, tells us how to weight all of the samples in  $\mathcal D$  to determine  $p(\mathbf x)$  at a particular  $\mathbf x$ .

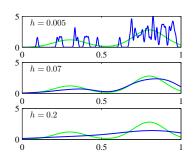

# **Example**

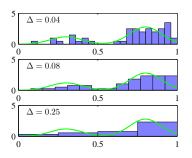

## **Example**

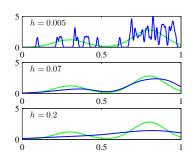

• But, what undesirable traits from histograms are inherited by Parzen window density estimates of the form we've just defined?

## **Example**

- But, what undesirable traits from histograms are inherited by Parzen window density estimates of the form we've just defined?
- Discontinuities...
- Dependence on the bandwidth.

## **Generalizing the Kernel Function**

- What if we allow a more general class of windowing functions rather than the hypercube?
- If we think of the windowing function as an interpolator, rather than considering the window function about  $\mathbf{x}$  only, we can visualize it as a kernel sitting on each data sample  $\mathbf{x}_i$  in  $\mathcal{D}$ .

## **Generalizing the Kernel Function**

- What if we allow a more general class of windowing functions rather than the hypercube?
- If we think of the windowing function as an interpolator, rather than considering the window function about  $\mathbf{x}$  only, we can visualize it as a kernel sitting on each data sample  $\mathbf{x}_i$  in  $\mathcal{D}$ .
- And, if we require the following two conditions on the kernel function  $\varphi$ , then we can be assured that the resulting density  $p_n(\mathbf{x})$  will be proper: non-negative and integrate to 1.

$$\varphi(\mathbf{x}) \ge 0 \tag{15}$$

$$\int \varphi(\mathbf{u}) d\mathbf{u} = 1 \tag{16}$$

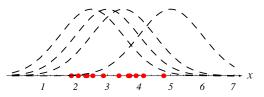

• For our previous case of  $V_n = h_n^d$ , then it follows  $p_n(\mathbf{x})$  will also satisfy these conditions.

◆ロト ◆昼 ト ◆ 差 ト → 差 ・ かへで

## **Example: A Univariate Guassian Kernel**

A popular choice of the kernel is the Gaussian kernel:

$$\varphi_h(u) = \frac{1}{\sqrt{2\pi}} \exp\left[-\frac{1}{2}u^2\right] \tag{17}$$

• The resulting density is given by:

$$p(x) = \frac{1}{n} \sum_{i=1}^{n} \frac{1}{h_n \sqrt{2\pi}} \exp\left[-\frac{1}{2h_n^2} (\mathbf{x} - \mathbf{x}_i)^2\right]$$
(18)

 It will give us smoother estimates without the discontinuites from the hypercube kernel.

## Effect of the Window Width

#### Slide I

- An important question is what effect does the window width  $h_n$  have on  $p_n(\mathbf{x})$ ?
- Define  $\delta_n(\mathbf{x})$  as

$$\delta_n(\mathbf{x}) = \frac{1}{V_n} \varphi\left(\frac{\mathbf{x}}{h_n}\right) \tag{19}$$

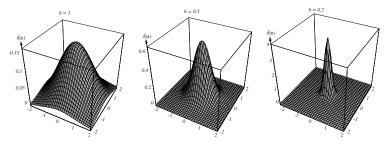

and rewrite  $p_n(\mathbf{x})$  as the average

$$p_n(\mathbf{x}) = \frac{1}{n} \sum_{i=1}^n \delta_n(\mathbf{x} - \mathbf{x}_i)$$
 (20)

## **Effect of the Window Width**

#### Slide II

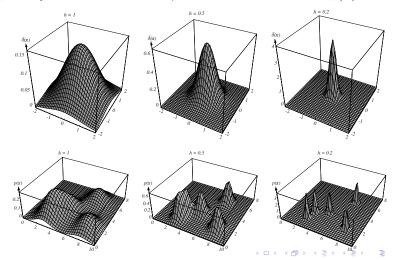

•  $h_n$  clearly affects both the amplitude and the width of  $\delta_n(\mathbf{x})$ .

## **Effect of the Window Width**

#### Slide II

•  $h_n$  clearly affects both the amplitude and the width of  $\delta_n(\mathbf{x})$ .

• But, for any value of  $h_n$ , the distribution is normalized:

$$\int \delta(\mathbf{x} - \mathbf{x}_i) d\mathbf{x} = \int \frac{1}{V_n} \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) d\mathbf{x} = \int \varphi(\mathbf{u}) d\mathbf{u} = 1$$
 (21)

• But, for any value of  $h_n$ , the distribution is normalized:

$$\int \delta(\mathbf{x} - \mathbf{x}_i) d\mathbf{x} = \int \frac{1}{V_n} \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) d\mathbf{x} = \int \varphi(\mathbf{u}) d\mathbf{u} = 1$$
 (21)

• If  $V_n$  is too large, the estimate will suffer from too little resolution.

• But, for any value of  $h_n$ , the distribution is normalized:

$$\int \delta(\mathbf{x} - \mathbf{x}_i) d\mathbf{x} = \int \frac{1}{V_n} \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) d\mathbf{x} = \int \varphi(\mathbf{u}) d\mathbf{u} = 1$$
 (21)

- ullet If  $V_n$  is too large, the estimate will suffer from too little resolution.
- If  $V_n$  is too small, the estimate will suffer from too much variability.

• But, for any value of  $h_n$ , the distribution is normalized:

$$\int \delta(\mathbf{x} - \mathbf{x}_i) d\mathbf{x} = \int \frac{1}{V_n} \varphi\left(\frac{\mathbf{x} - \mathbf{x}_i}{h_n}\right) d\mathbf{x} = \int \varphi(\mathbf{u}) d\mathbf{u} = 1$$
 (21)

- ullet If  $V_n$  is too large, the estimate will suffer from too little resolution.
- ullet If  $V_n$  is too small, the estimate will suffer from too much variability.
- In theory (with an unlimited number of samples), we can let  $V_n$  slowly approach zero as n increases and then  $p_n(\mathbf{x})$  will converge to the unknown  $p(\mathbf{x})$ . But, in practice, we can, at best, seek some compromise.

# **Example: Revisiting the Univariate Guassian Kernel**

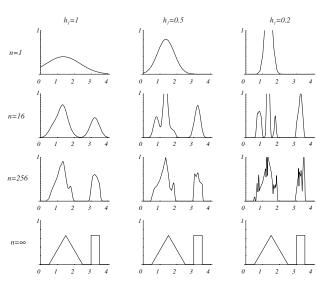

$$n = \infty$$

# **Example: A Bimodal Distribution**

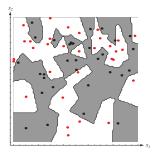

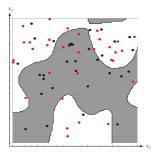

## Parzen Window-Based Classifiers

- Estimate the densities for each category.
- Classify a query point by the label corresponding to the maximum posterior (i.e., one can include priors).

## Parzen Window-Based Classifiers

- Estimate the densities for each category.
- Classify a query point by the label corresponding to the maximum posterior (i.e., one can include priors).
- As you guessed it, the decision regions for a Parzen window-based classifier depend upon the kernel function.

#### Parzen Window-Based Classifiers

- During training, we can make the error arbitrarily low by making the window sufficiently small, but this will have an ill-effect during testing (which is our ultimate need).
- Think of any possibilities for system rules of choosing the kernel?

#### Parzen Window-Based Classifiers

- During training, we can make the error arbitrarily low by making the window sufficiently small, but this will have an ill-effect during testing (which is our ultimate need).
- Think of any possibilities for system rules of choosing the kernel?
- One possibility is to use cross-validation. Break up the data into a training set and a validation set. Then, perform training on the training set with varying bandwidths. Select the bandwidth that minimizes the error on the validation set.

#### Parzen Window-Based Classifiers

- During training, we can make the error arbitrarily low by making the window sufficiently small, but this will have an ill-effect during testing (which is our ultimate need).
- Think of any possibilities for system rules of choosing the kernel?
- One possibility is to use cross-validation. Break up the data into a training set and a validation set. Then, perform training on the training set with varying bandwidths. Select the bandwidth that minimizes the error on the validation set.
- There is little theoretical justification for choosing one window width over another.

# $k_n$ Nearest Neighbor Methods

- Selecting the best window / bandwidth is a severe limiting factor for Parzen window estimators.
- $k_n$ -NN methods circumvent this problem by making the window size a function of the actual training data.

# $k_n$ Nearest Neighbor Methods

- Selecting the best window / bandwidth is a severe limiting factor for Parzen window estimators.
- $k_n$ -NN methods circumvent this problem by making the window size a function of the actual training data.
- The basic idea here is to center our window around  ${\bf x}$  and let it grow until it captures  $k_n$  samples, where  $k_n$  is a function of n.
  - These samples are the  $k_n$  nearest neighbors of  ${\bf x}$ .
  - $\bullet$  If the density is high near x then the window will be relatively small leading to good resolution.
  - If the density is low near x, the window will grow large, but it will stop soon after it enters regions of higher density.

# $k_n$ Nearest Neighbor Methods

- Selecting the best window / bandwidth is a severe limiting factor for Parzen window estimators.
- $k_n$ -NN methods circumvent this problem by making the window size a function of the actual training data.
- The basic idea here is to center our window around x and let it grow until it captures  $k_n$  samples, where  $k_n$  is a function of n.
  - These samples are the  $k_n$  nearest neighbors of  ${\bf x}$ .
  - If the density is high near x then the window will be relatively small leading to good resolution.
  - If the density is low near x, the window will grow large, but it will stop soon after it enters regions of higher density.
  - In either case, we estimate  $p_n(\mathbf{x})$  according to

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n} \tag{22}$$

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n}$$

• We want  $k_n$  to go to infinity as n goes to infinity thereby assuring us that  $k_n/n$  will be a good estimate of the probability that a point will fall in the window of volume  $V_n$ .

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n}$$

- We want  $k_n$  to go to infinity as n goes to infinity thereby assuring us that  $k_n/n$  will be a good estimate of the probability that a point will fall in the window of volume  $V_n$ .
- But, we also want  $k_n$  to grow sufficiently slowly so that the size of our window will go to zero.

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n}$$

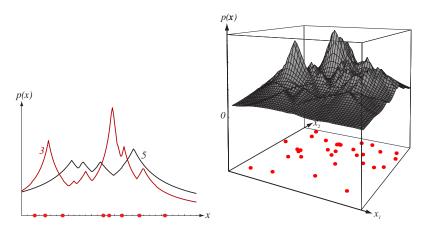

- We want  $k_n$  to go to infinity as n goes to infinity thereby assuring us that  $k_n/n$  will be a good estimate of the probability that a point will fall in the window of volume  $V_n$ .
- But, we also want  $k_n$  to grow sufficiently slowly so that the size of our window will go to zero.
- Thus, we want  $k_n/n$  to go to zero.

$$p_n(\mathbf{x}) = \frac{k_n}{nV_n}$$

- We want  $k_n$  to go to infinity as n goes to infinity thereby assuring us that  $k_n/n$  will be a good estimate of the probability that a point will fall in the window of volume  $V_n$ .
- But, we also want  $k_n$  to grow sufficiently slowly so that the size of our window will go to zero.
- Thus, we want  $k_n/n$  to go to zero.
- Recall these conditions from the earlier discussion; these will ensure that  $p_n(\mathbf{x})$  converges to  $p(\mathbf{x})$  as n approaches infinity.

## Examples of $k_n$ -NN Estimation

• Notice the discontinuities in the slopes of the estimate.

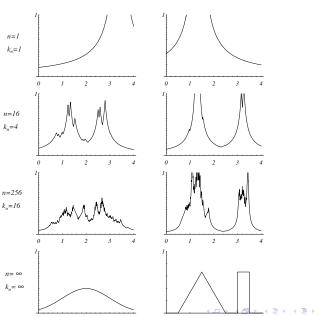

## k-NN Estimation From 1 Sample

- We don't expect the density estimate from 1 sample to be very good, but in the case of k-NN it will diverge!
- With n=1 and  $k_n=\sqrt{n}=1$ , the estimate for  $p_n(x)$  is

$$p_n(x) = \frac{1}{2|x - x_1|} \tag{23}$$

But, as we increase the number of samples, the estimate will improve.

• The  $k_n$ -NN Estimator suffers from an analogous flaw from which the Parzen window methods suffer. What is it?

- The  $k_n$ -NN Estimator suffers from an analogous flaw from which the Parzen window methods suffer. What is it?
- How do we specify the k<sub>n</sub>?
- We saw earlier that the specification of  $k_n$  can lead to radically different density estimates (in practical situations where the number of training samples is limited).

- The  $k_n$ -NN Estimator suffers from an analogous flaw from which the Parzen window methods suffer. What is it?
- How do we specify the  $k_n$ ?
- We saw earlier that the specification of  $k_n$  can lead to radically different density estimates (in practical situations where the number of training samples is limited).
- One could obtain a sequence of estimates by taking  $k_n = k_1 \sqrt{n}$  and choose different values of  $k_1$ .

- The  $k_n$ -NN Estimator suffers from an analogous flaw from which the Parzen window methods suffer. What is it?
- How do we specify the  $k_n$ ?
- We saw earlier that the specification of  $k_n$  can lead to radically different density estimates (in practical situations where the number of training samples is limited).
- One could obtain a sequence of estimates by taking  $k_n = k_1 \sqrt{n}$  and choose different values of  $k_1$ .
- But, like the Parzen window size, one choice is as good as another absent any additional information.

- The  $k_n$ -NN Estimator suffers from an analogous flaw from which the Parzen window methods suffer. What is it?
- How do we specify the  $k_n$ ?
- We saw earlier that the specification of  $k_n$  can lead to radically different density estimates (in practical situations where the number of training samples is limited).
- One could obtain a sequence of estimates by taking  $k_n=k_1\sqrt{n}$  and choose different values of  $k_1$ .
- But, like the Parzen window size, one choice is as good as another absent any additional information.
- Similarly, in classification scenarios, we can base our judgement on classification error.

• We can directly apply the k-NN methods to estimate the posterior probabilities  $P(\omega_i|\mathbf{x})$  from a set of n labeled samples.

- We can directly apply the k-NN methods to estimate the posterior probabilities  $P(\omega_i|\mathbf{x})$  from a set of n labeled samples.
- Place a window of volume V around  $\mathbf{x}$  and capture k samples, with  $k_i$  turning out to be of label  $\omega_i$ .

- We can directly apply the k-NN methods to estimate the posterior probabilities  $P(\omega_i|\mathbf{x})$  from a set of n labeled samples.
- Place a window of volume V around  $\mathbf{x}$  and capture k samples, with  $k_i$  turning out to be of label  $\omega_i$ .
- The estimate for the joint probability is thus

$$p_n(\mathbf{x}, \omega_i) = \frac{k_i}{nV} \tag{24}$$

- We can directly apply the k-NN methods to estimate the posterior probabilities  $P(\omega_i|\mathbf{x})$  from a set of n labeled samples.
- Place a window of volume V around  $\mathbf x$  and capture k samples, with  $k_i$  turning out to be of label  $\omega_i$ .
- The estimate for the joint probability is thus

$$p_n(\mathbf{x}, \omega_i) = \frac{k_i}{nV} \tag{24}$$

A reasonable estimate for the posterior is thus

$$P_n(\omega_i|\mathbf{x}) = \frac{p_n(\mathbf{x}, \omega_i)}{\sum_c p_n(\mathbf{x}, \omega_c)} = \frac{k_i}{k}$$
 (25)

- We can directly apply the k-NN methods to estimate the posterior probabilities  $P(\omega_i|\mathbf{x})$  from a set of n labeled samples.
- Place a window of volume V around  $\mathbf x$  and capture k samples, with  $k_i$  turning out to be of label  $\omega_i$ .
- The estimate for the joint probability is thus

$$p_n(\mathbf{x}, \omega_i) = \frac{k_i}{nV} \tag{24}$$

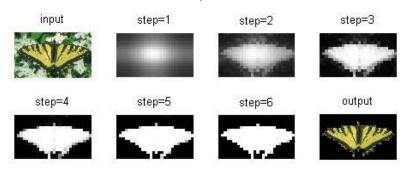

A reasonable estimate for the posterior is thus

$$P_n(\omega_i|\mathbf{x}) = \frac{p_n(\mathbf{x}, \omega_i)}{\sum_c p_n(\mathbf{x}, \omega_c)} = \frac{k_i}{k}$$
 (25)

• Hence, the posterior probability for  $\omega_i$  is simply the fraction of samples within the window that are labeled  $\omega_i$ . This is a simple and intuitive result.

### **Example: Figure-Ground Discrimination**

- Figure-ground discrimination is an important low-level vision task.
- Want to separate the pixels that contain some foreground object (specified in some meaningful way) from the background.

## **Example: Figure-Ground Discrimination**

- This paper presents a method for figure-ground discrimination based on non-parametric densities for the foreground and background.
- They use a subset of the pixels from each of the two regions.
- They propose an algorithm called iterative sampling-expectation for performing the actual segmentation.
- The required input is simply a region of interest (mostly) containing the object.

## **Example: Figure-Ground Discrimination**

Source: Zhao and Davis. Iterative Figure-Ground Discrimination. ICPR 2004.

- Given a set of n samples  $S = \{x_i\}$  where each  $x_i$  is a d-dimensional vector.
- We know the kernel density estimate is defined as

$$\hat{p}(\mathbf{y}) = \frac{1}{n\sigma_1 \dots \sigma_d} \sum_{i=1}^n \prod_{j=1}^d \varphi\left(\frac{\mathbf{y}_j - \mathbf{x}_{ij}}{\sigma_j}\right)$$
(26)

where the same kernel  $\varphi$  with different bandwidth  $\sigma_j$  is used in each dimension.

## The Representation

Source: Zhao and Davis. Iterative Figure-Ground Discrimination. ICPR 2004.

The representation used here is a function of RGB:

$$r = R/(R+G+B) \tag{27}$$

$$g = G/(R+G+B) \tag{28}$$

$$s = (R + G + B)/3 (29)$$

- Separating the chromaticity from the brightness allows them to us a wider bandwidth in the brightness dimension to account for variability due to shading effects.
- ullet And, much narrower kernels can be used on the r and g chromaticity channels to enable better discrimination.

## The Color Density

Source: Zhao and Davis. Iterative Figure-Ground Discrimination. ICPR 2004.

• Given a sample of pixels  $S = \{ \mathbf{x}_i = (r_i, g_i, s_i) \}$ , the color density estimate is given by

$$\hat{P}(\mathbf{x} = (r, g, s)) = \frac{1}{n} \sum_{i=1}^{n} K_{\sigma_r}(r - r_i) K_{\sigma_g}(g - g_i) K_{\sigma_s}(s - s_i)$$
 (30)

where we have simplified the kernel definition:

$$K_{\sigma}(t) = \frac{1}{\sigma} \varphi\left(\frac{t}{\sigma}\right) \tag{31}$$

They use Gaussian kernels

$$K_{\sigma}(t) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left[-\frac{1}{2} \left(\frac{t}{\sigma}\right)^{2}\right]$$
 (32)

with a different bandwidth in each dimension.

#### **Data-Driven Bandwidth**

Source: Zhao and Davis. Iterative Figure-Ground Discrimination. ICPR 2004.

 The bandwidth for each channel is calculated directly from the image based on sample statistics.

$$\sigma \approx 1.06 \hat{\sigma} n^{-1/5} \tag{33}$$

where  $\hat{\sigma}^2$  is the sample variance.

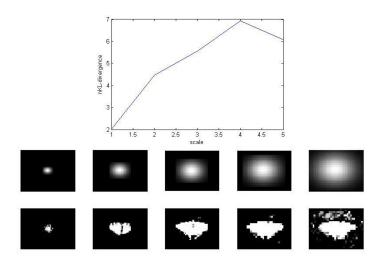

# Initialization: Choosing the Initial Scale

Source: Zhao and Davis. Iterative Figure-Ground Discrimination. ICPR 2004.

- For initialization, they compute a distance between the foreground and background distribution by varying the scale of a single Gaussian kernel (on the foreground).
- To evaluate the "significance" of a particular scale, they compute the normalized KL-divergence:

$$\mathsf{nKL}(\hat{P}_{fg}||\hat{P}_{bg}) = \frac{-\sum_{i=1}^{n} \hat{P}_{fg}(\mathbf{x}_i) \log \frac{\hat{P}_{fg}(\mathbf{x}_i)}{\hat{P}_{bg}(\mathbf{x}_i)}}{\sum_{i=1}^{n} \hat{P}_{fg}(\mathbf{x}_i)}$$
(34)

where  $\hat{P}_{fg}$  and  $\hat{P}_{bg}$  are the density estimates for the foreground and background regions respectively. To compute each, they use about 6% of the pixels (using all of the pixels would lead to quite slow performance).

## **Iterative Sampling-Expectation Algorithm**

- Given the initial segmentation, they need to refine the models and labels to adapt better to the image.
- However, this is a chicken-and-egg problem. If we know the labels, we could compute the models, and if we knew the models, we could compute the best labels.

## **Iterative Sampling-Expectation Algorithm**

- Given the initial segmentation, they need to refine the models and labels to adapt better to the image.
- However, this is a chicken-and-egg problem. If we know the labels, we could compute the models, and if we knew the models, we could compute the best labels.
- They propose an EM algorithm for this. The basic idea is to alternate between estimating the probability that each pixel is of the two classes, and then given this probability to refine the underlying models.
- EM is guaranteed to converge (but only to a local minimum).

1 Initialize using the normalized KL-divergence.

- Initialize using the normalized KL-divergence.
- Uniformly sample a set of pixel from the image to use in the kernel density estimation. This is essentially the 'M' step (because we have a non-parametric density).

- Initialize using the normalized KL-divergence.
- Uniformly sample a set of pixel from the image to use in the kernel density estimation. This is essentially the 'M' step (because we have a non-parametric density).
- Update the pixel assignment based on maximum likelihood (the 'E' step).

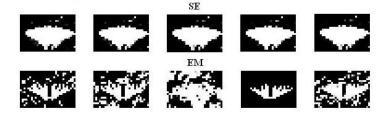

- Initialize using the normalized KL-divergence.
- Uniformly sample a set of pixel from the image to use in the kernel density estimation. This is essentially the 'M' step (because we have a non-parametric density).
- Update the pixel assignment based on maximum likelihood (the 'E' step).
- Repeat until stable.
