

## CSE491/596 Wed. 9/20/23: Non-Regular Languages

Rather than the "Pumping Lemma", we will employ the **Myhill-Nerode Theorem** (MNT) to prove non-regularity of certain languages. Although it was proved in Chicago in 1957-58 where John Myhill and Anil Nerode were students, we can claim it as Western NY heritage: Myhill was a professor at UB until his death in 1987, and Anil Nerode still teaches at Cornell past age 90(!) Nerode was my supervisor when I had a postdoc at Cornell.

### Building up to the Proof

Given a DFA  $M = (Q, \Sigma, \delta, s, F)$  and two strings  $x, y \in \Sigma^*$ , suppose  $\delta^*(s, x)$  and  $\delta^*(s, y)$  both give the same state  $q$ . Then for any further string  $z \in \Sigma^*$ , the computations on the strings  $xz$  and  $yz$  go through the same states after  $q$ . In particular, they end at the same state  $r$ .

- If  $r \in F$ , then  $xz \in L$  and  $yz \in L$ , where  $L = L(M)$ .
- If  $r \notin F$ , then  $xz \notin L$  and  $yz \notin L$ .
- Either way,  $L(xz) = L(yz)$ , for all  $z$ .

Suppose, on the other hand, we have strings  $x, y$  for which **there exists a string  $z$**  such that

$$L(xz) \neq L(yz).$$

Then  $M$  cannot process  $x$  and  $y$  to the same state. Moreover, this goes for *any* DFA  $M$  such that  $L(M) = L$ . In particular, every such DFA must at least *have* two states.

Now let us build some definitions around these ideas. Given any language  $L$  (not necessarily regular) and strings  $x, y$  "over" the alphabet  $\Sigma$  that  $L$  is "over", define:

- $x$  and  $y$  are  *$L$ -equivalent*, written  $x \sim_L y$ , if **for all**  $z \in \Sigma^*$ ,  $L(xz) = L(yz)$ .
- $x$  and  $y$  are *distinctive for  $L$* , written  $x \not\sim_L y$ , if **there exists**  $z \in \Sigma^*$  s.t.  $L(xz) \neq L(yz)$ .

**Lemma 1.** The relation  $\sim_L$  is an equivalence relation.

Proof: We need to show that it is

- Reflexive:  $x \sim_L x$  is obvious.
- Symmetric: indeed,  $y \sim_L x$  immediately means the same as  $x \sim_L y$ .
- Transitive: Suppose  $w \sim_L x$  and  $x \sim_L y$ . This means:
  - for all  $v \in \Sigma^*$ ,  $L(wv) = L(xv)$  and
  - for all  $z \in \Sigma^*$ ,  $L(xz) = L(yz)$ .Because  $v$  and  $z$  range over the same span of strings, it *follows* that
  - for all  $z \in \Sigma^*$ ,  $L(wz) = L(xz)$  and  $L(xz) = L(yz)$ .

Hence we get:

– for all  $z \in \Sigma^*$ ,  $L(wz) = L(yz)$ .

So  $w \sim_L y$ .

This ends the proof.  $\square$

Any equivalence relation on a set such as  $\Sigma^*$  partitions that set into disjoint *equivalence classes*. So  $x \not\sim_L y$  is the same as saying  $x$  and  $y$  belong to different equivalence classes.

Now say that a set  $S$  of strings is **Pairwise Distinctive for  $L$**  if all of its strings belong to separate equivalence classes under the relation  $\sim_L$ . Other names we will use are "distinctive set" and "PD set" for  $L$ . This is the same as saying:

- for all  $x, y \in S$ ,  $x \neq y$ , there exists  $z \in \Sigma^*$  such that  $L(xz) \neq L(yz)$ .

Thus we can re-state something we said above as:

**Lemma 2.** If  $L$  has a PD set  $S$  of size 2, then any DFA  $M$  such that  $L(M) = L$  must process the two strings in  $S$  to different states, so  $M$  must have at least 2 states.

Note: " $L$  has" does not mean  $S$  must be a subset of  $L$ , it just means "has by association." Now we can take this logic further:

**Lemma  $k$ .** If  $L$  has a PD set  $S$  of size  $k$ , then any DFA  $M$  such that  $L(M) = L$  must process the  $k$  strings in  $S$  to different states, so  $M$  must have at least  $k$  states.

I've worded this to try to make it as "obvious" as possible, but actually it needs proof: Suppose we have a DFA  $M$  with  $k - 1$  or fewer states such that  $L(M) = L$ . Then there must be (at least) two strings in  $S$  that  $M$  processes to the same state. This follows by the **Pigeonhole Principle**. [\[story from GLL blog\]](#)

**Lemma  $\infty$ .** If  $L$  has a PD set  $S$  of size  $\infty$ , then any DFA  $M$  such that  $L(M) = L$  must process the strings in  $S$  to different states, so  $M$  must have at least  $\infty$  states...but then  $M$  is not a *finite* automaton. So  $L$  is not accepted by any finite automaton...which means  **$L$  is not a regular language**.  $\square$

**Myhill-Nerode Theorem**, first half: If  $L$  has an infinite PD set, then  $L$  is not regular.

**Example 1:**  $L = \{a^n b^n : n \geq 0\}$ .  $\Sigma = \{a, b\}$ .  $S = \{a^n : n \geq 0\} = a^*$ . Let any  $x, y \in S$ ,  $x \neq y$ , be given. Then there are different numbers  $i$  and  $j$  such that  $x = a^i$  and  $y = a^j$ . Take  $z = b^i$ . Then  $xz = a^i b^i \in L$ , but  $yz = a^j b^i \notin L$ , because  $i \neq j$ . Thus  $L(xz) \neq L(yz)$ . Thus for all  $x, y \in S$  with  $x \neq y$ , there exists  $z$  such that  $L(xz) \neq L(yz)$ . Thus  $S$  is PD for  $L$ . Since  $S$  is infinite,  $L$  is not regular, by MNT.  $\square$

We have proved only one direction of the Myhill-Nerode Theorem:  $L$  has an infinite PD set  $\implies L$  is nonregular, but this is the direction to apply for nonregularity proofs. Those proofs can all be made to follow a "script":

**Take**  $S = \underline{\hspace{2cm}}$ . [Observe  $S$  is infinite---this is usually immediately clear.]

**Let any**  $x, y \in S$  ( $x \neq y$ ) **be given**. Then we can write  $x = \underline{\hspace{2cm}}$  and  $y = \underline{\hspace{2cm}}$  where  $\underline{\hspace{2cm}}$  [and **without loss of generality**,  $\underline{\hspace{2cm}}$ ].

**Take**  $z = \underline{\hspace{2cm}}$ .

Then  $L(xz) \neq L(yz)$  because  $\underline{\hspace{2cm}}$

Because  $x, y$  are an arbitrary pair of strings in  $S$ , this shows that  $S$  is PD for  $L$ , and since  $S$  is infinite, it follows that  $L$  is nonregular by the Myhill-Nerode Theorem.

I have colored the words **take** and **let...be given** separately to show how they express the logical quantifiers in the formal statement of this direction of MNT:

**If there exists** an infinite set  $S$  such that **for all** distinct  $x, y \in S$  **there exists**  $z \in \Sigma^*$  such that  $L(xz) \neq L(yz)$ , **then**  $L$  is nonregular.

The difference is that *you* have control of choices in the existential parts, but in the "for-all" parts you have to be prepared for all possibilities. There is a habit to use "let" in both situations, but this can be confusing. [Give humorous story about how both "let" and "any" are self-contradictory words in English, but they are OK together with "...be given."] Now let's re-do Example 1 with the script:

**Example 1.**  $L = \{a^n b^n : n \geq 0\}$ .

**Take**  $S = \underline{\hspace{1cm}}a^*\underline{\hspace{1cm}}$ . [Observe  $S$  is infinite---this is usually immediately clear.]

**Let any**  $x, y \in S$  ( $x \neq y$ ) **be given**. Then we can write  $x = \underline{\hspace{1cm}}a^i\underline{\hspace{1cm}}$  and  $y = \underline{\hspace{1cm}}a^j\underline{\hspace{1cm}}$  where  $\underline{\hspace{1cm}}i \neq j$  (and it is understood that  $i, j \geq 0$ ) $\underline{\hspace{1cm}}$  [and **without loss of generality**,  $\underline{\hspace{1cm}}$ ].

**Take**  $z = \underline{\hspace{1cm}}b^i\underline{\hspace{1cm}}$ .

Then  $L(xz) \neq L(yz)$  because  $\underline{\hspace{1cm}}xz = a^i b^i$  which is in  $L$  since the counts are equal, but  $yz = a^j b^i$  which is not in  $L$  because  $j$  is different from  $i$ .

Because  $x, y$  are an arbitrary pair of strings in  $S$ , this shows that  $S$  is PD for  $L$ , and since  $S$  is infinite, it follows that  $L$  is nonregular by the Myhill-Nerode Theorem.

Thus to prove a given  $L$  nonregular we have to "act out" the proof---and the above is our script. The first example also illustrates the optional "w.l.o.g." clause.

**Example 2.**  $L = \{x \in \{s, d\}^* : \#s(x) \geq \#d(x)\}$ .

**Take**  $S = \_s^*\_$ . Clearly  $S$  is infinite.

**Let any**  $x, y \in S$  ( $x \neq y$ ) **be given**. Then we can write  $x = \_s^i\_$  and  $y = \_s^j\_$  where  $\_i \neq j\_$  and **wlog.**,  $\_j < i\_$ .

**Take**  $z = \_d^i\_$ .

Then  $L(xz) \neq L(yz)$  because  $\_xz = s^i d^i \in L\_$ . Whereas  $yz = s^j d^i \dots$  is not in  $L$  because wlog.  $j < i$ .

Because  $x, y$  are an arbitrary pair of strings in  $S$ , this shows that  $S$  is PD for  $L$ , and since  $S$  is infinite, it follows that  $L$  is nonregular by the Myhill-Nerode Theorem.

Note that this  $L$  is not the same as the language of "spears-and-dragons with unlimited saving of spears" because e.g. the string " $ds$ " belongs to this  $L$  despite the spear coming too late in the other. But the *proof* is exactly the same. The fun is that not only do these proofs become fairly automatic once you get comfortable with the script, they are often like re-usable code.

[Here and/or with *reductions*, I used to say for fun that this can be an exception to the university rule against recycling an old answer for a new assignment, even when it was your answer. I even used to sing a relevant section of the Tom Lehrer song "Lobachevsky" which you can find linked at <https://gilkalai.wordpress.com/2020/08/29/to-cheer-you-up-in-difficult-times-11-immortal-songs-by-sabine-hossenfelder-and-by-tom-lehrer/>. But an upsurge in academic integrity violations made this all stop being funny about 15 years ago...]
