CSE 341 Review

ISA and Programming

Instruction Set

- The repertoire of instructions of a computer
- Different computers have different instruction sets
  - But with many aspects in common
- Early computers had very simple instruction sets
  - Simplified implementation
- Many modern computers also have simple instruction sets

The MIPS Instruction Set

- Used as the example throughout the book
- Stanford MIPS commercialized by MIPS Technologies (www.mips.com)
- Large share of embedded core market
  - Applications in consumer electronics, network/storage equipment, cameras, printers, …
- Typical of many modern ISAs
  - See MIPS Reference Data tear-out card, and Appendixes B and E

Arithmetic Operations

- Add and subtract, three operands
  - Two sources and one destination

```
add a, b, c   # a gets b + c
```

- All arithmetic operations have this form
- *Design Principle 1:* Simplicity favours regularity
  - Regularity makes implementation simpler
  - Simplicity enables higher performance at lower cost

Arithmetic Example

- C code:

```
f = (g + h) - (i + j);
```

- Compiled MIPS code:

```
add t0, g, h   # temp t0 = g + h
add t1, i, j   # temp t1 = i + j
sub f, t0, t1  # f = t0 - t1
```

Register Operands

- Arithmetic instructions use register operands
- MIPS has a 32 × 32-bit register file
  - Use for frequently accessed data
  - Numbered 0 to 31
  - 32-bit data called a “word”
- Assembler names
  - $t0, $t1, …, $t9 for temporary values
  - $s0, $s1, …, $s7 for saved variables
- *Design Principle 2:* Smaller is faster
  - c.f. main memory: millions of locations

Register Operand Example

- C code:

```
f = (g + h) - (i + j);
```

  - f, …, j in $s0, …, $s4

- Compiled MIPS code:

```
add $t0, $s1, $s2
add $t1, $s3, $s4
sub $s0, $t0, $t1
```

Memory Operands

- Main memory used for composite data
  - Arrays, structures, dynamic data
- To apply arithmetic operations
  - Load values from memory into registers
  - Store result from register to memory
- Memory is byte addressed
  - Each address identifies an 8-bit byte
- Words are aligned in memory
  - Address must be a multiple of 4
- MIPS is Big Endian
  - Most-significant byte at least address of a word
  - *c.f.* Little Endian: least-significant byte at least address

Memory Operand Example 1

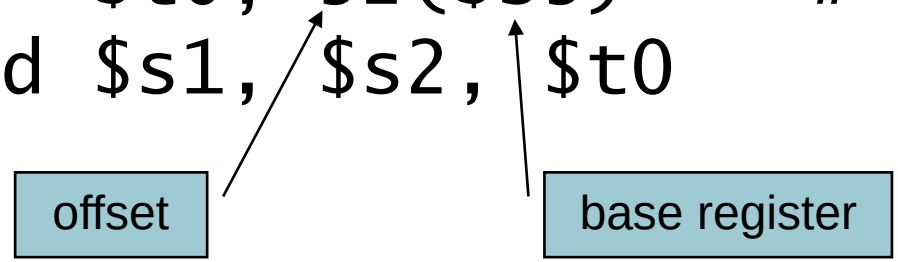
- C code:

```
g = h + A[8];
```

  - g in $s1, h in $s2, base address of A in $s3

- Compiled MIPS code:
  - Index 8 requires offset of 32
    - 4 bytes per word

```
lw  $t0, 32($s3)     # load word
add $s1, $s2, $t0
```



Memory Operand Example 2

- C code:

```
A[12] = h + A[8];
```

  - h in $s2, base address of A in $s3

- Compiled MIPS code:
  - Index 8 requires offset of 32

```
lw  $t0, 32($s3)    # load word
add $t0, $s2, $t0
sw  $t0, 48($s3)    # store word
```

Registers vs. Memory

- Registers are faster to access than memory
- Operating on memory data requires loads and stores
  - More instructions to be executed
- Compiler must use registers for variables as much as possible
  - Only spill to memory for less frequently used variables
  - Register optimization is important!

Immediate Operands

- Constant data specified in an instruction

```
addi $s3, $s3, 4
```

- No subtract immediate instruction
  - Just use a negative constant

```
addi $s2, $s1, -1
```

- *Design Principle 3:* Make the common case fast
  - Small constants are common
  - Immediate operand avoids a load instruction

The Constant Zero

- MIPS register 0 ($zero) is the constant 0
  - Cannot be overwritten
- Useful for common operations
  - E.g., move between registers

```
add $t2, $s1, $zero
```

2s-Complement Signed Integers

- Bit 31 is sign bit
  - 1 for negative numbers
  - 0 for non-negative numbers
- $-(-2^{n-1})$ can't be represented
- Non-negative numbers have the same unsigned and 2s-complement representation
- Some specific numbers
  - 0: 0000 0000 … 0000
  - –1: 1111 1111 … 1111
  - Most-negative: 1000 0000 … 0000
  - Most-positive: 0111 1111 … 1111

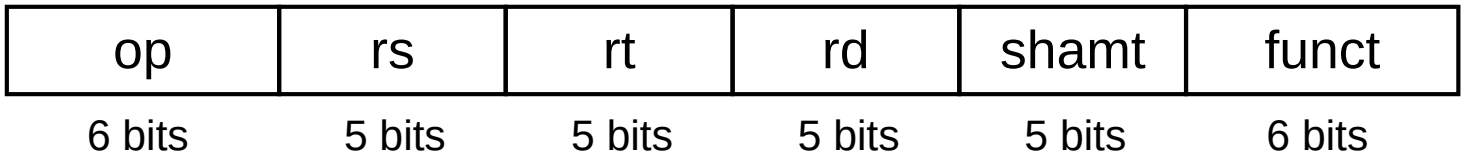
Sign Extension

- Representing a number using more bits
  - Preserve the numeric value
- In MIPS instruction set
  - `addi`: extend immediate value
  - `lb`, `lh`: extend loaded byte/halfword
  - `beq`, `bne`: extend the displacement
- Replicate the sign bit to the left
  - c.f. unsigned values: extend with 0s
- Examples: 8-bit to 16-bit
  - +2: 0000 0010 => 0000 0000 0000 0010
  - –2: 1111 1110 => 1111 1111 1111 1110

Representing Instructions

- Instructions are encoded in binary
  - Called machine code
- MIPS instructions
  - Encoded as 32-bit instruction words
  - Small number of formats encoding operation code (opcode), register numbers, …
  - Regularity!
- Register numbers
  - $t0 – $t7 are reg's 8 – 15
  - $t8 – $t9 are reg's 24 – 25
  - $s0 – $s7 are reg's 16 – 23

MIPS R-format Instructions



- Instruction fields
  - op: operation code (opcode)
  - rs: first source register number
  - rt: second source register number
  - rd: destination register number
  - shamt: shift amount (00000 for now)
  - funct: function code (extends opcode)

R-format Example

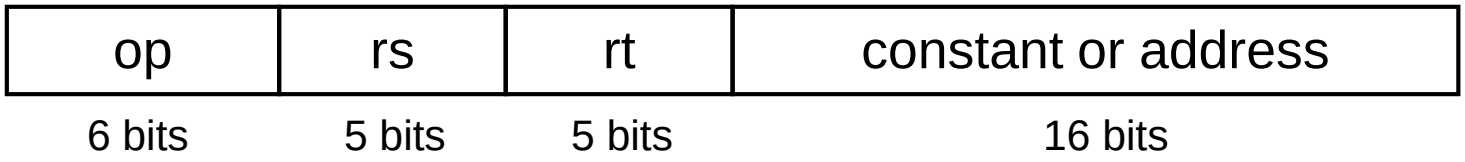
op	rs	rt	rd	shamt	funct
6 bits	5 bits	5 bits	5 bits	5 bits	6 bits

```
add $t0, $s1, $s2
```

special	$s1	$s2	$t0	0	add
0	17	18	8	0	32
000000	10001	10010	01000	00000	100000

$$00000010001100100100000000100000_2 = 02324020_{16}$$

MIPS I-format Instructions



- Immediate arithmetic and load/store instructions
  - rt: destination or source register number
  - Constant: -2^{15} to $+2^{15} - 1$
  - Address: offset added to base address in rs
- *Design Principle 4:* Good design demands good compromises
  - Different formats complicate decoding, but allow 32-bit instructions uniformly
  - Keep formats as similar as possible

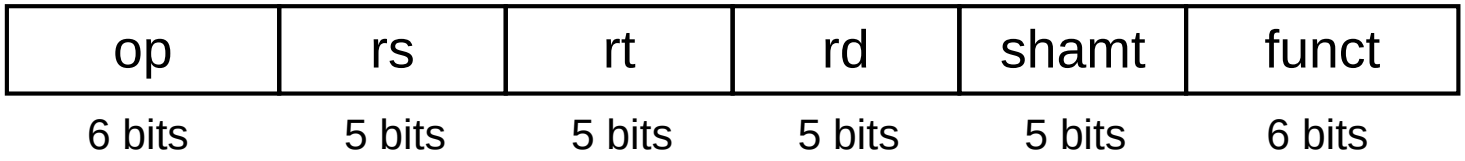
Logical Operations

- Instructions for bitwise manipulation

Operation	C	Java	MIPS
Shift left	<<	<<	sll
Shift right	>>	>>>	srl
Bitwise AND	&	&	and, andi
Bitwise OR	|	|	or, ori
Bitwise NOT	~	~	nor

- Useful for extracting and inserting groups of bits in a word

Shift Operations

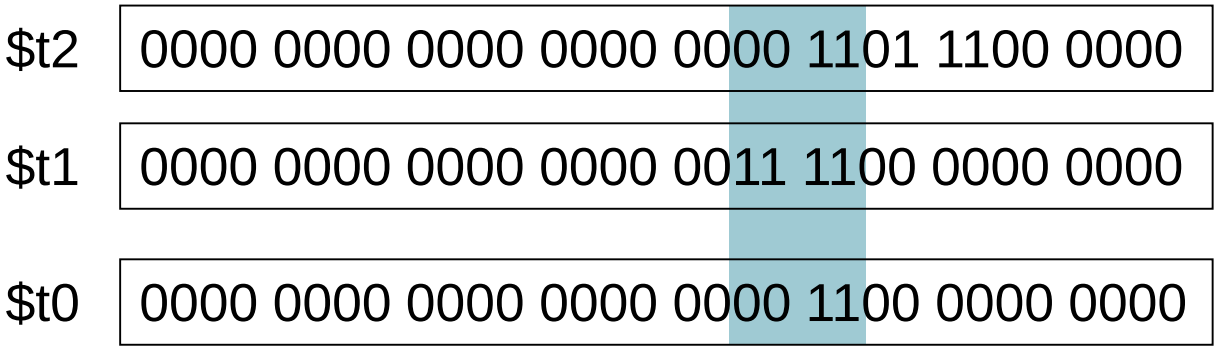


- shamt: how many positions to shift
- Shift left logical
  - Shift left and fill with 0 bits
  - `sll` by *i* bits multiplies by 2^i
- Shift right logical
  - Shift right and fill with 0 bits
  - `srl` by *i* bits divides by 2^i (unsigned only)

AND Operations

- Useful to mask bits in a word
  - Select some bits, clear others to 0

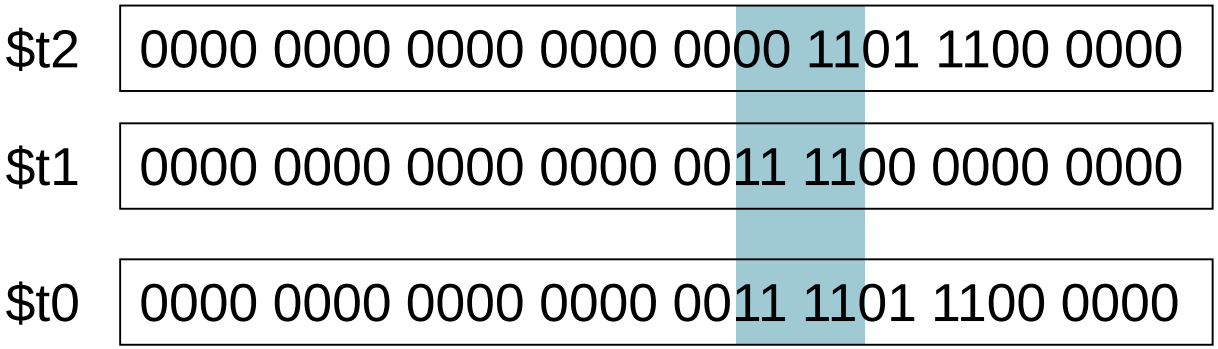
```
and $t0, $t1, $t2
```



OR Operations

- Useful to include bits in a word
  - Set some bits to 1, leave others unchanged

```
or $t0, $t1, $t2
```



NOT Operations

- Useful to invert bits in a word
  - Change 0 to 1, and 1 to 0
- MIPS has NOR 3-operand instruction
  - a NOR b == NOT (a OR b)

```
nor $t0, $t1, $zero
```

Register 0: always read as zero

$t1	0000 0000 0000 0000 0011 1100 0000 0000
$t0	1111 1111 1111 1111 1100 0011 1111 1111

Conditional Operations

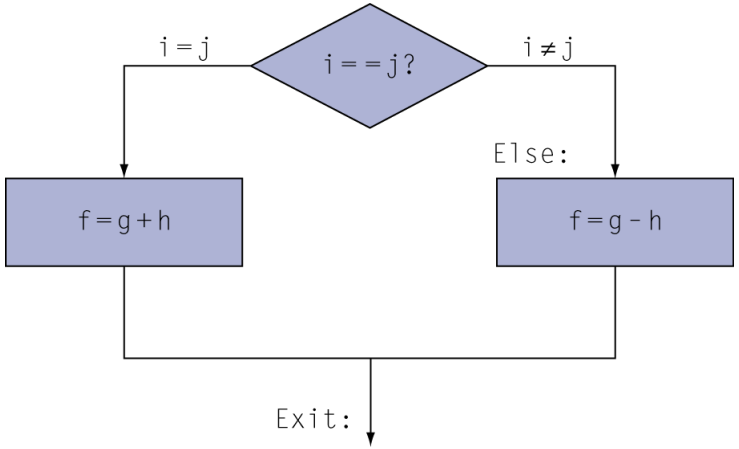
- Branch to a labeled instruction if a condition is true
  - Otherwise, continue sequentially
- `beq rs, rt, L1`
  - if (rs == rt) branch to instruction labeled `L1`;
- `bne rs, rt, L1`
  - if (rs != rt) branch to instruction labeled `L1`;
- `j L1`
  - unconditional jump to instruction labeled L1

Compiling If Statements

- C code:

```
if (i==j) f = g+h;
else f = g-h;
```

  - f, g, … in $s0, $s1, …



- Compiled MIPS code:

```
      bne $s3, $s4, Else
      add $s0, $s1, $s2
      j   Exit
Else: sub $s0, $s1, $s2
Exit: …
```

Assembler calculates addresses

Compiling Loop Statements

- C code:

```
while (save[i] == k) i += 1;
```

  - i in $s3, k in $s5, address of save in $s6
- Compiled MIPS code:

```
Loop: sll  $t1, $s3, 2
      add  $t1, $t1, $s6
      lw   $t0, 0($t1)
      bne  $t0, $s5, Exit
      addi $s3, $s3, 1
      j    Loop
Exit: …
```

More Conditional Operations

- Set result to 1 if a condition is true
  - Otherwise, set to 0
- `slt rd, rs, rt`
  - if (rs < rt) rd = 1; else rd = 0;
- `slti rt, rs, constant`
  - if (rs < constant) rt = 1; else rt = 0;
- Use in combination with `beq`, `bne`

```
slt $t0, $s1, $s2  # if ($s1 < $s2)
bne $t0, $zero, L  #   branch to L
```

Branch Instruction Design

- Why not `blt`, `bge`, etc?
- Hardware for <, ≥, … slower than =, ≠
  - Combining with branch involves more work per instruction, requiring a slower clock
  - All instructions penalized!
- `beq` and `bne` are the common case
- This is a good design compromise

Signed vs. Unsigned

- Signed comparison: `slt`, `slti`
- Unsigned comparison: `sltu`, `sltui`
- Example
  - $s0 = 1111 1111 1111 1111 1111 1111 1111 1111
  - $s1 = 0000 0000 0000 0000 0000 0000 0000 0001
  - `slt  $t0, $s0, $s1  # signed`
    - –1 < +1 ⇒ $t0 = 1
  - `sltu $t0, $s0, $s1  # unsigned`
    - +4,294,967,295 > +1 ⇒ $t0 = 0

Procedure Calling

- Steps required
  1. Place parameters in registers
  2. Transfer control to procedure
  3. Acquire storage for procedure
  4. Perform procedure's operations
  5. Place result in register for caller
  6. Return to place of call

Register Usage

- $a0 – $a3: arguments (reg's 4 – 7)
- $v0, $v1: result values (reg's 2 and 3)
- $t0 – $t9: temporaries
  - Can be overwritten by callee
- $s0 – $s7: saved
  - Must be saved/restored by callee
- $gp: global pointer for static data (reg 28)
- $sp: stack pointer (reg 29)
- $fp: frame pointer (reg 30)
- $ra: return address (reg 31)

Procedure Call Instructions

- Procedure call: jump and link

  `jal ProcedureLabel`

  - Address of following instruction put in $ra
  - Jumps to target address
- Procedure return: jump register

  `jr $ra`

  - Copies $ra to program counter
  - Can also be used for computed jumps
    - e.g., for case/switch statements

Leaf Procedure Example

- C code:

```
int leaf_example (int g, h, i, j)
{ int f;
  f = (g + h) - (i + j);
  return f;
}
```

  - Arguments g, …, j in $a0, …, $a3
  - f in $s0 (hence, need to save $s0 on stack)
  - Result in $v0

Leaf Procedure Example

- MIPS code:

`leaf_example:`	
`addi $sp, $sp, -4` `sw $s0, 0($sp)`	Save $s0 on stack

`add $t0, $a0, $a1`
`add $t1, $a2, $a3`
`sub $s0, $t0, $t1`
	Procedure body

`add $v0, $s0, $zero`	Result
`lw $s0, 0($sp)` `addi $sp, $sp, 4`	Restore $s0
`jr $ra`	Return

Non-Leaf Procedures

- Procedures that call other procedures
- For nested call, caller needs to save on the stack:
  - Its return address
  - Any arguments and temporaries needed after the call
- Restore from the stack after the call

Non-Leaf Procedure Example

- C code:

```
int fact (int n)
{
  if (n < 1) return f;
  else return n * fact(n - 1);
}
```

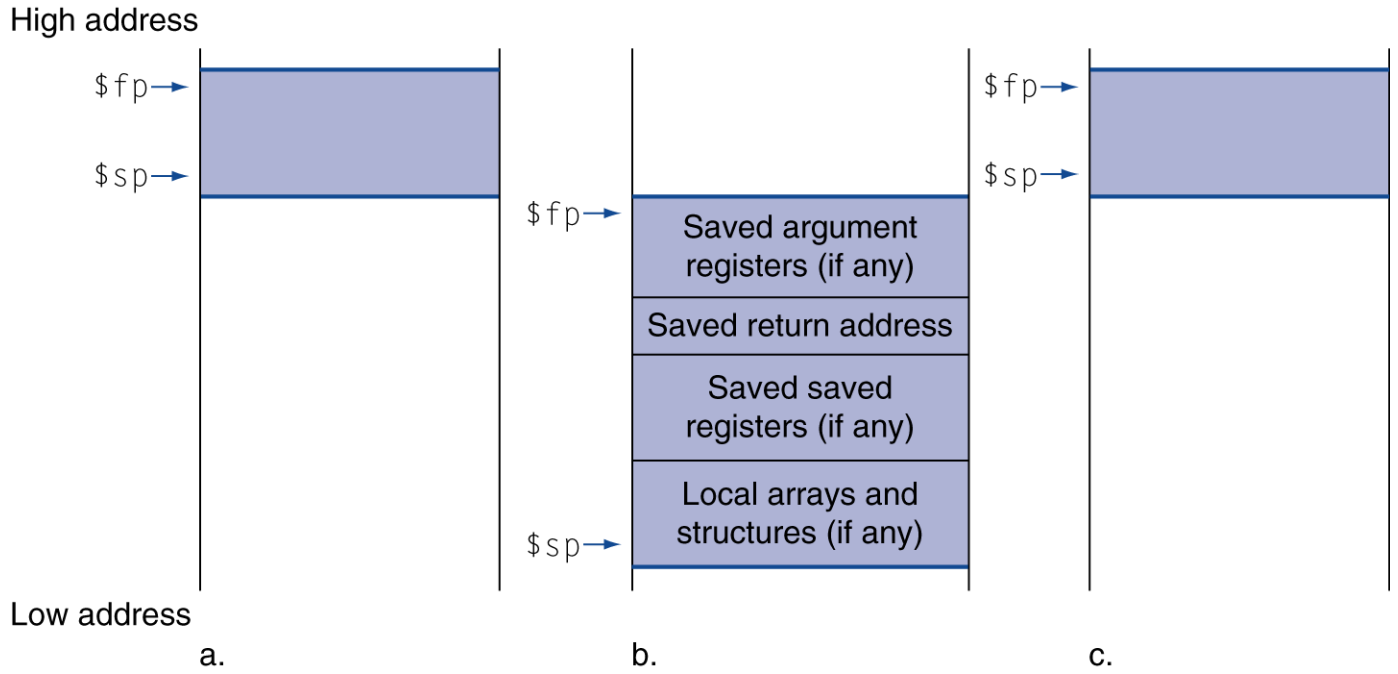
  - Argument n in $a0
  - Result in $v0

Non-Leaf Procedure Example

- MIPS code:

```
fact:
    addi $sp, $sp, -8       # adjust stack for 2 items
    sw   $ra, 4($sp)        # save return address
    sw   $a0, 0($sp)        # save argument
    slti $t0, $a0, 1        # test for n < 1
    beq  $t0, $zero, L1
    addi $v0, $zero, 1      # if so, result is 1
    addi $sp, $sp, 8        #   pop 2 items from stack
    jr   $ra                #   and return
L1: addi $a0, $a0, -1       # else decrement n
    jal  fact               # recursive call
    lw   $a0, 0($sp)        # restore original n
    lw   $ra, 4($sp)        #   and return address
    addi $sp, $sp, 8        # pop 2 items from stack
    mul  $v0, $a0, $v0      # multiply to get result
    jr   $ra                # and return
```

Local Data on the Stack



- Local data allocated by callee
  - e.g., C automatic variables
- Procedure frame (activation record)
  - Used by some compilers to manage stack storage

Byte/Halfword Operations

- Could use bitwise operations
- MIPS byte/halfword load/store
  - String processing is a common case

```
lb rt, offset(rs)      lh rt, offset(rs)
```

  - Sign extend to 32 bits in rt

```
lbu rt, offset(rs)     lhu rt, offset(rs)
```

  - Zero extend to 32 bits in rt

```
sb rt, offset(rs)      sh rt, offset(rs)
```

  - Store just rightmost byte/halfword

32-bit Constants

- Most constants are small
  - 16-bit immediate is sufficient
- For the occasional 32-bit constant

  `lui rt, constant`
  - Copies 16-bit constant to left 16 bits of rt
  - Clears right 16 bits of rt to 0

```
lhi $s0, 61
```

0000 0000 0111 1101	0000 0000 0000 0000

```
ori $s0, $s0, 2304
```

0000 0000 0111 1101	0000 1001 0000 0000

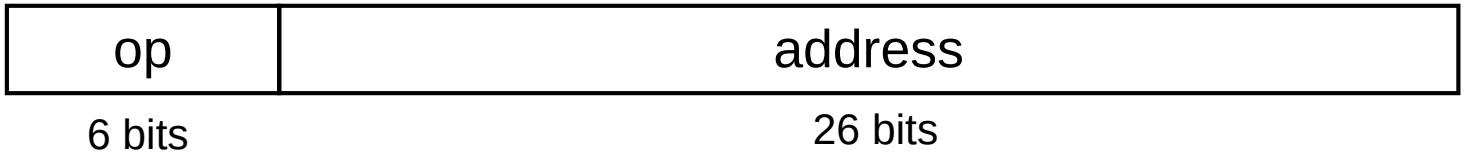
Branch Addressing

- Branch instructions specify
  - Opcode, two registers, target address
- Most branch targets are near branch
  - Forward or backward

  - PC-relative addressing
    - Target address = PC + offset × 4
    - PC already incremented by 4 by this time

Jump Addressing

- Jump (`j` and `jal`) targets could be anywhere in text segment
  - Encode full address in instruction



- (Pseudo)Direct jump addressing
  - Target address = $PC_{31\ldots28}$: (address × 4)

Target Addressing Example

- Loop code from earlier example
  - Assume Loop at location 80000

```
Loop: sll  $t1, $s3, 2
      add  $t1, $t1, $s6
      lw   $t0, 0($t1)
      bne  $t0, $s5, Exit
      addi $s3, $s3, 1
      j    Loop
Exit: …
```

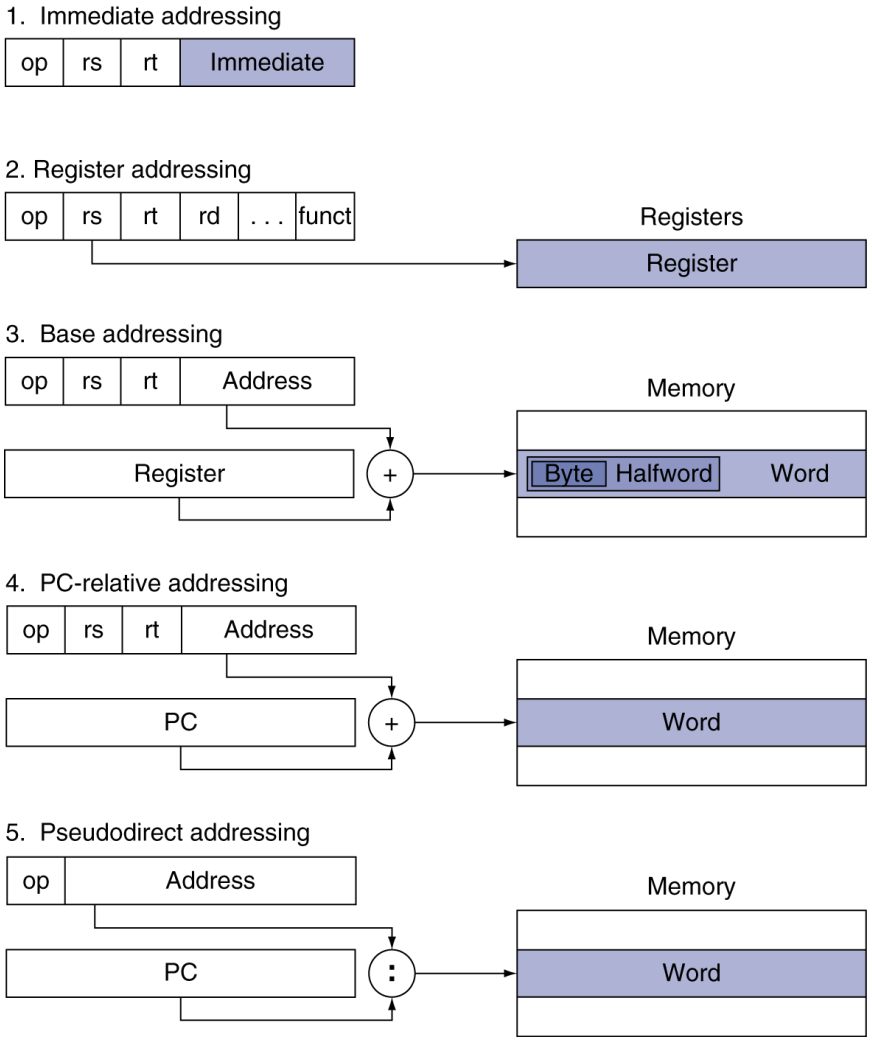
80000	0	0	19	9	4	0
80004	0	9	22	9	0	32
80008	35	9	8	0		
80012	5	8	21	2		
80016	8	19	19	1		
80020	2	20000				
80024						

Branching Far Away

- If branch target is too far to encode with 16-bit offset, assembler rewrites the code
- Example

```
        beq $s0,$s1, L1
              ↓
        bne $s0,$s1, L2
        j L1
  L2: …
```

Addressing Mode Summary

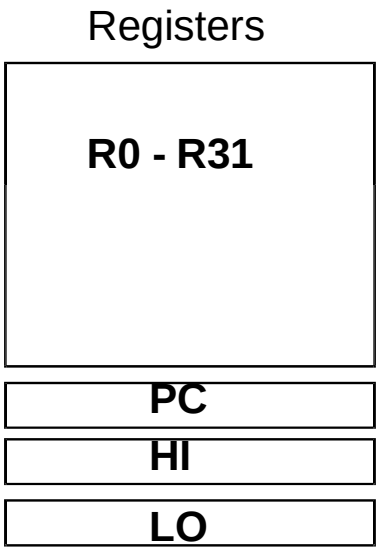


Green sheet

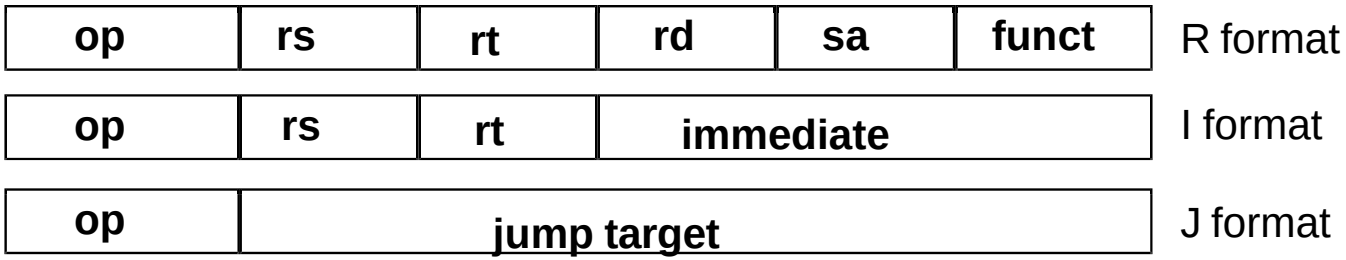
Review

MIPS-32 ISA

- Instruction Categories
  - Computational
  - Load/Store
  - Jump and Branch
  - Floating Point
    - coprocessor
  - Memory Management
  - Special



3 Instruction Formats: all 32 bits wide



MIPS ArithmeticInstructions

- MIPS assembly language arithmetic statement

```
add   $t0, $s1, $s2
sub   $t0, $s1, $s2
```

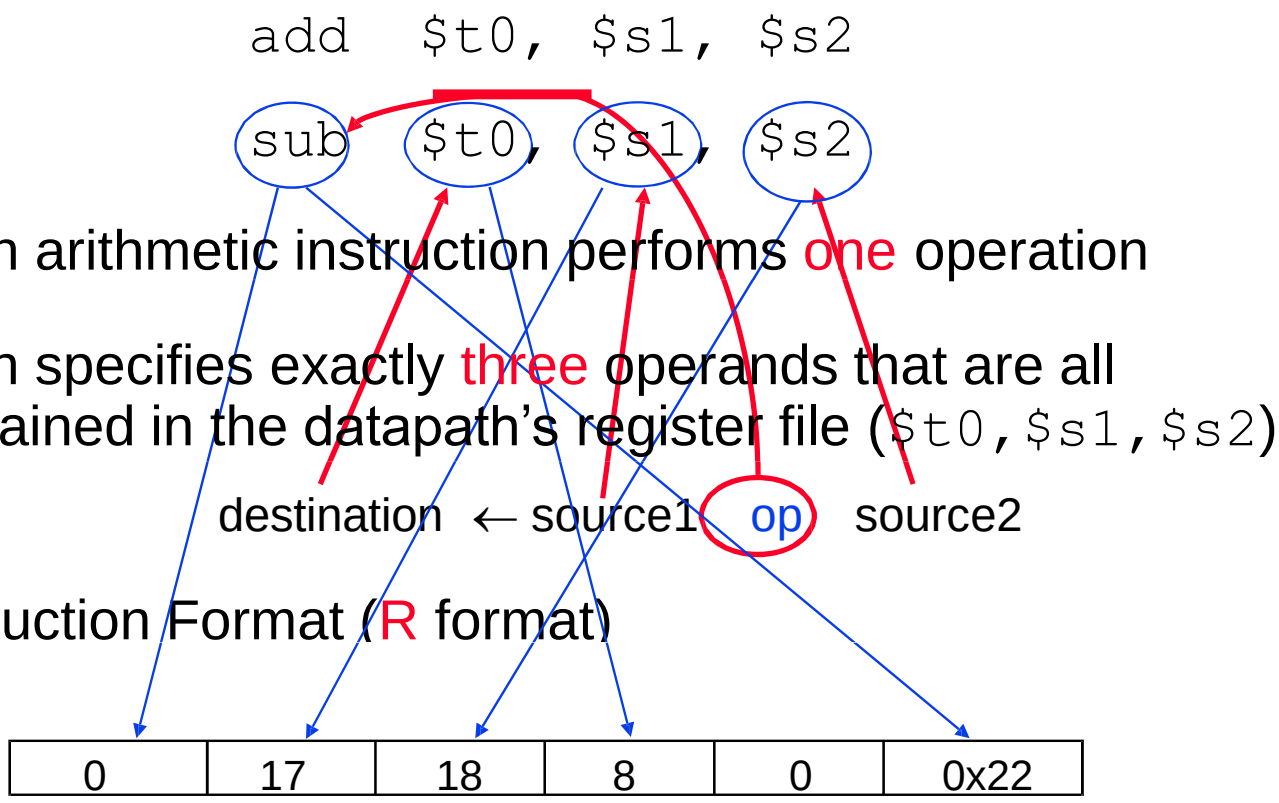
- Each arithmetic instruction performs one operation
- Each specifies exactly three operands that are all contained in the datapath's register file (`$t0,$s1,$s2`)

destination ← source1 op source2

- Instruction Format (R format)

MIPS Arithmetic Instructions

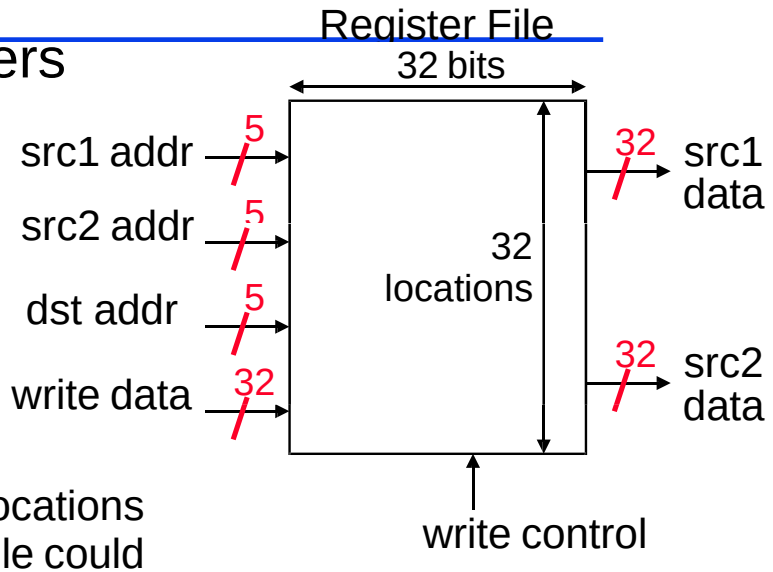
- MIPS assembly language arithmetic statement



- Each arithmetic instruction performs one operation
- Each specifies exactly three operands that are all contained in the datapath's register file (`$t0,$s1,$s2`)
- Instruction Format (R format)

MIPS Register File

- Holds thirty-two 32-bit registers
  - Two read ports and
  - One write port



- Registers are
  - Faster than main memory
    - But register files with more locations are slower (e.g., a 64 word file could be as much as 50% slower than a 32 word file)
    - Read/write port increase impacts speed quadratically
  - Easier for a compiler to use
    - e.g., (A*B) – (C*D) – (E*F) can do multiplies in any order vs. stack
  - Can hold variables so that
    - code density improves (since register are named with fewer bits than a memory location)

Aside: MIPS RegisterConvention

Name	Register Number	Usage	Preserve on call?
$zero	0	constant 0 (hardware)	n.a.
$at	1	reserved for assembler	n.a.
$v0 - $v1	2-3	returned values	no
$a0 - $a3	4-7	arguments	yes
$t0 - $t7	8-15	temporaries	no
$s0 - $s7	16-23	saved values	yes
$t8 - $t9	24-25	temporaries	no
$gp	28	global pointer	yes
$sp	29	stack pointer	yes
$fp	30	frame pointer	yes
$ra	31	return addr (hardware)	yes

MIPS Memory Access Instructions

- MIPS has two basic data transfer instructions for accessing memory

```
lw   $t0, 4($s3)   #load word from memory

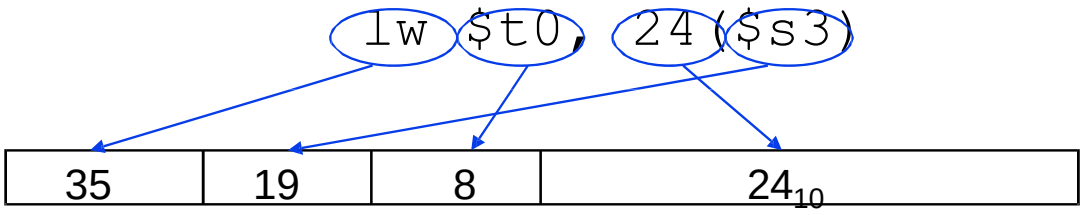
sw   $t0, 8($s3)   #store word to memory
```

- The data is loaded into (lw) or stored from (sw) a register in the register file – a 5 bit address

- The memory address – a 32 bit address – is formed by adding the contents of the base address register to the offset value
  - A 16-bit field meaning access is limited to memory locations within a region of $\pm 2^{13}$ or 8,192 words ($\pm 2^{15}$ or 32,768 bytes) of the address in the base register

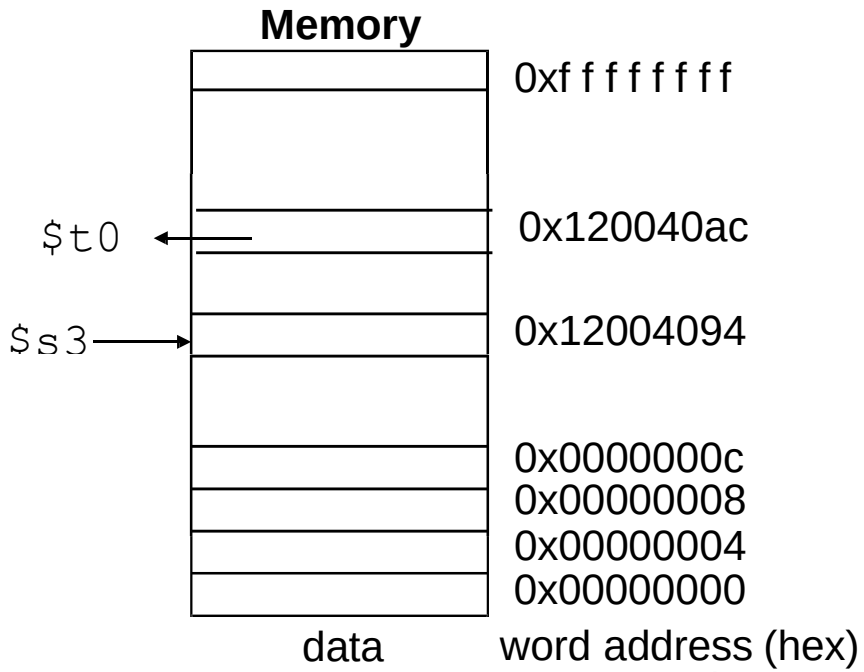
Machine Language – Load Instruction

- Load/Store Instruction Format (I format):



24_{10} + $s3 =

. . . 0001 1000
+ . . . 1001 0100
. . . 1010 1100 =
0x120040ac

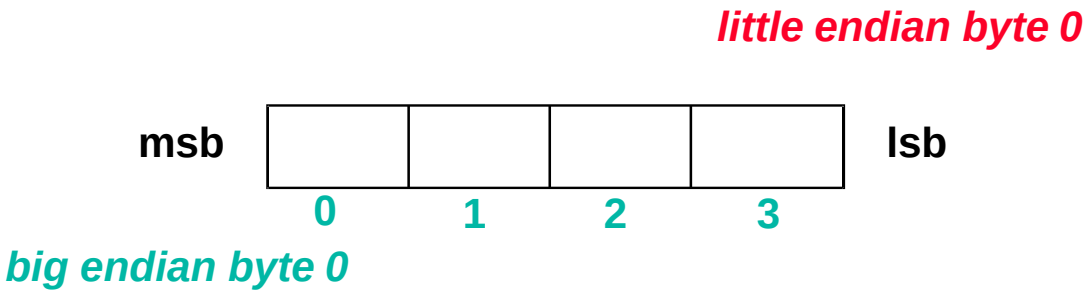


ByteAddresses

- Since 8-bit bytes are so useful, most architectures address individual bytes in memory
  - Alignment restriction - the memory address of a word must be on natural word boundaries (a multiple of 4 in MIPS-32)
- Big Endian: leftmost byte is word address

  IBM 360/370, Motorola 68k, MIPS, Sparc, HP PA
- Little Endian: rightmost byte is word address

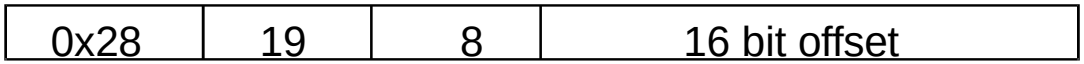
  Intel 80x86, DEC Vax, DEC Alpha (Windows NT)



Aside: Loading and Storing Bytes

- MIPS provides special instructions to move bytes

```
lb   $t0, 1($s3)  #load byte from memory
sb   $t0, 6($s3)  #store byte to  memory
```



- What 8 bits get loaded and stored?
  - load byte places the byte from memory in the rightmost 8 bits of the destination register
    - what happens to the other bits in the register?
  - store byte takes the byte from the rightmost 8 bits of a register and writes it to a byte in memory
    - what happens to the other bits in the memory word?

MIPS Immediate Instructions

- Small constants are used often in typical code
- Possible approaches?
  - put “typical constants” in memory and load them
  - create hard-wired registers (like $zero) for constants like 1
  - have special instructions that contain constants !

```
addi $sp, $sp, 4      #$sp = $sp + 4

slti $t0, $s2, 15     #$t0 = 1 if $s2<15
```

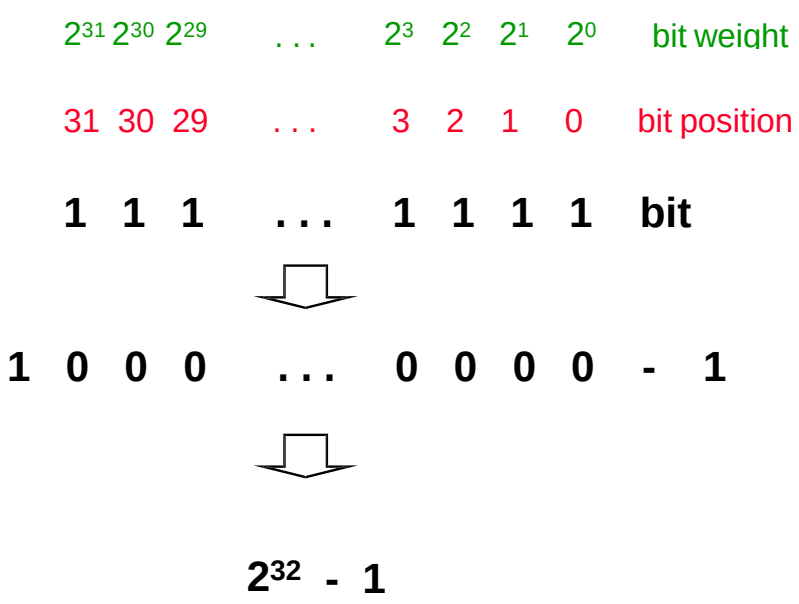
- Machine format (I format):

0x0A	18	8	0x0F

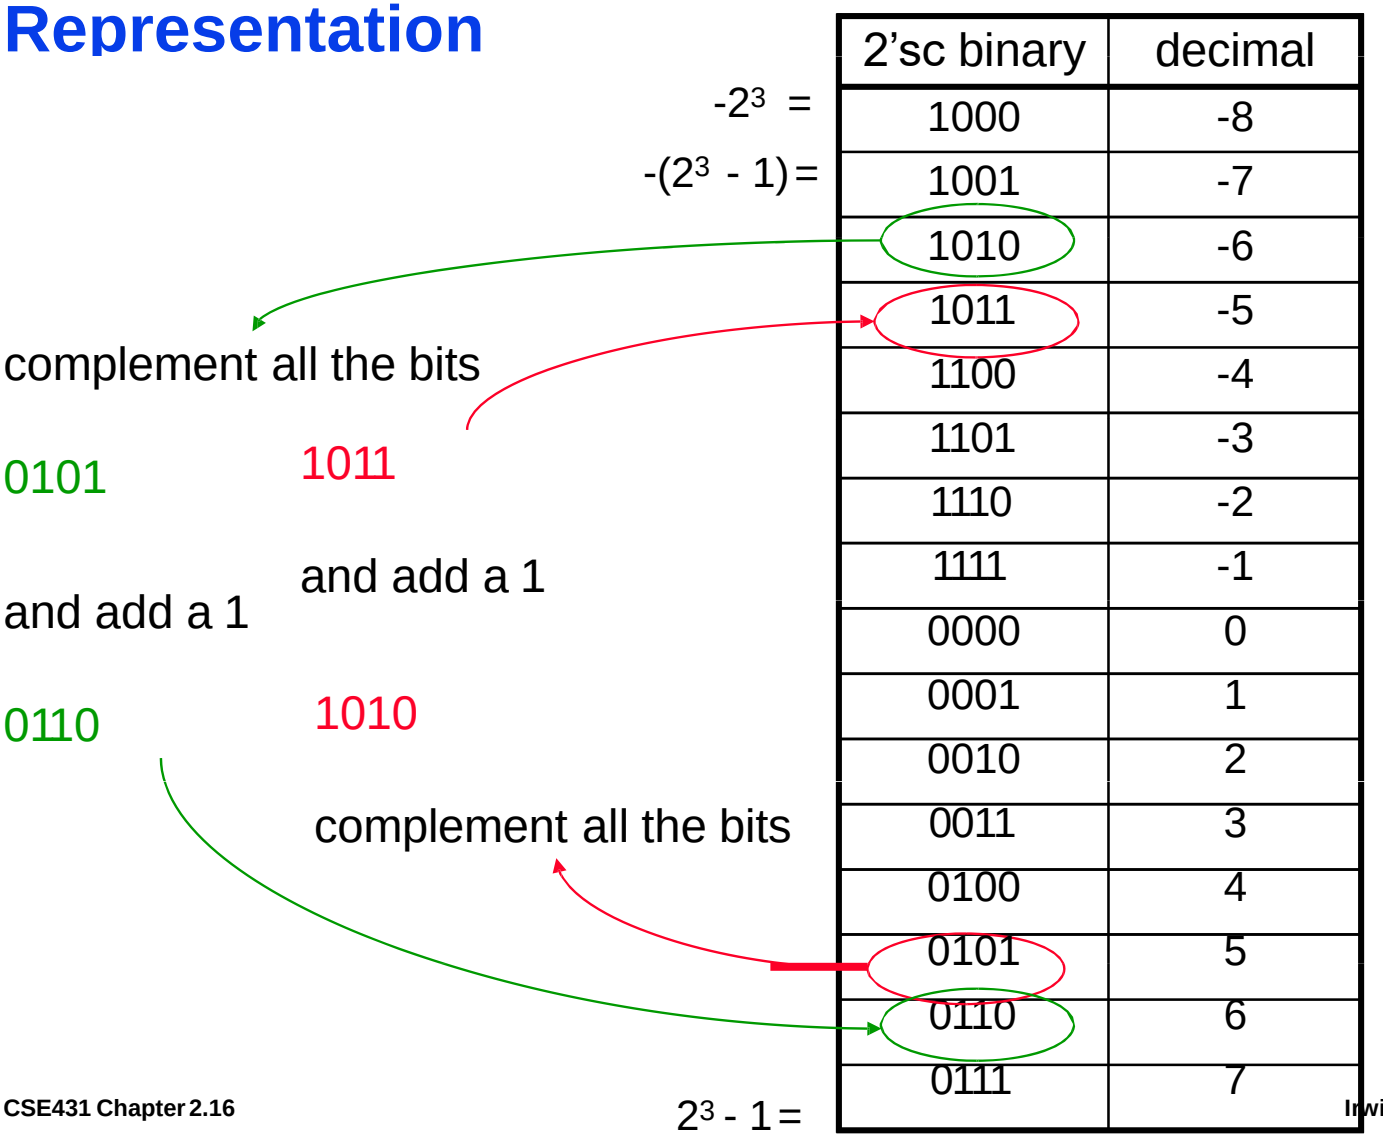
- The constant is kept inside the instruction itself!
  - Immediate format limits values to the range $+2^{15}-1$ to -2^{15}

Review: Unsigned Binary Representation

Hex	Binary	Decimal
0x00000000	0…0000	0
0x00000001	0…0001	1
0x00000002	0…0010	2
0x00000003	0…0011	3
0x00000004	0…0100	4
0x00000005	0…0101	5
0x00000006	0…0110	6
0x00000007	0…0111	7
0x00000008	0…1000	8
0x00000009	0…1001	9
	…	
0xFFFFFFFC	1…1100	$2^{32} - 4$
0xFFFFFFFD	1…1101	$2^{32} - 3$
0xFFFFFFFE	1…1110	$2^{32} - 2$
0xFFFFFFFF	1…1111	$2^{32} - 1$



Review: Signed Binary Representation

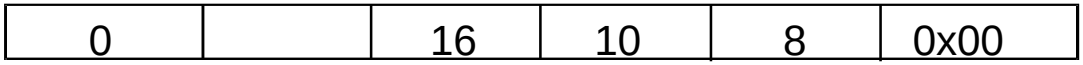


MIPS Shift Operations

- Need operations to pack and unpack 8-bit characters into 32-bit words
- Shifts move all the bits in a word left or right

```
sll $t2, $s0, 8    #$t2 = $s0 << 8 bits
srl $t2, $s0, 8    #$t2 = $s0 >> 8 bits
```

- Instruction Format (R format)



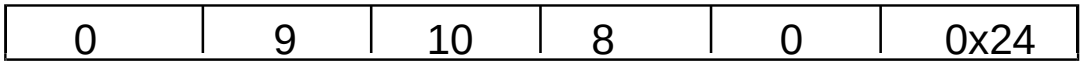
- Such shifts are called logical because they fill with zeros
  - Notice that a 5-bit shamt field is enough to shift a 32-bit value $2^5 - 1$ or 31 bit positions

MIPS Logical Operations

- There are a number of bit-wise logical operations in the MIPS ISA

```
and $t0, $t1, $t2  #$t0 = $t1 & $t2
or  $t0, $t1, $t2  #$t0 = $t1 | $t2
nor $t0, $t1, $t2 #$t0 = not($t1 | $t2)
```

- Instruction Format (R format)



```
andi $t0, $t1, 0xFF00   #$t0 = $t1 & ff00
ori  $t0, $t1, 0xFF00   #$t0 = $t1 | ff00
```

- Instruction Format (I format)

MIPS Control Flow Instructions

- MIPS conditional branch instructions:

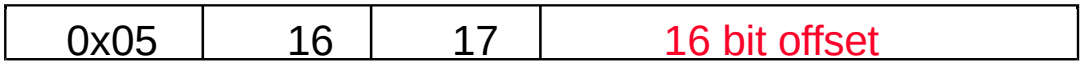
```
bne $s0, $s1, Lbl #go to Lbl if $s0≠$s1
beq $s0, $s1, Lbl #go to Lbl if $s0=$s1
```

  - Ex:

```
        if (i==j) h = i + j;

        bne $s0, $s1, Lbl1
        add $s3, $s0, $s1
Lbl1:   ...
```

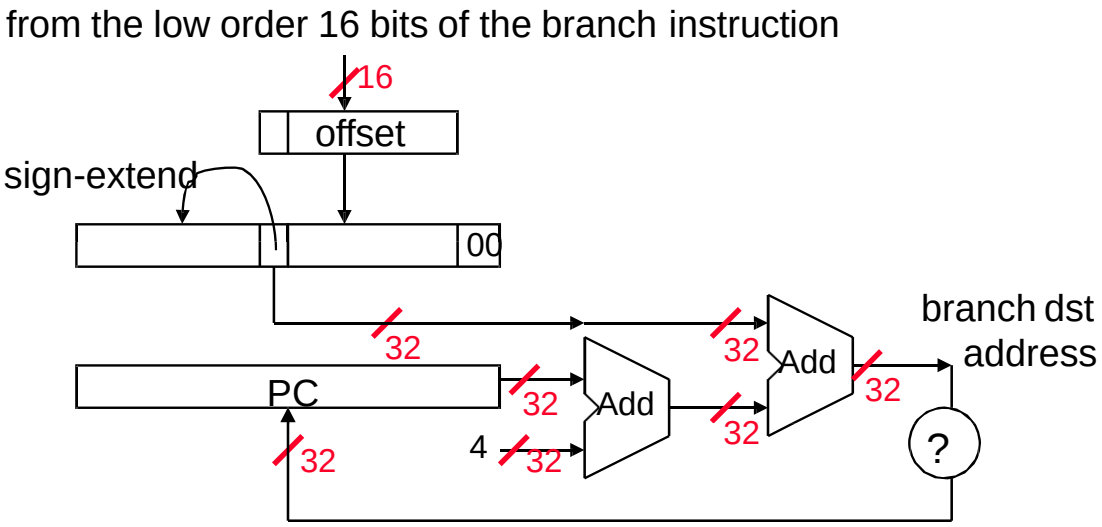
- Instruction Format (I format):



- How is the branch destination address specified?

Specifying Branch Destinations

- Use a register (like in lw and sw) added to the 16-bit offset
  - which register? Instruction Address Register (the PC)
    - its use is automatically implied by instruction
    - PC gets updated (PC+4) during the fetch cycle so that it holds the address of the next instruction
  - limits the branch distance to -2^{15} to $+2^{15}-1$ (word) instructions from the (instruction after the) branch instruction, but most branches are local anyway



In Support of Branch Instructions

- We have `beq`, `bne`, but what about other kinds of branches (e.g., branch-if-less-than)? For this, we need yet another instruction, `slt`
- Set on less than instruction:

```
slt $t0, $s0, $s1     # if $s0 < $s1     then
                      # $t0 = 1          else
                      # $t0 = 0
```

- Instruction format (R format):

- Alternate versions of `slt`

```
slti $t0, $s0, 25     # if $s0 < 25 then $t0=1 ...
sltu $t0, $s0, $s1    # if $s0 < $s1 then $t0=1 ...
sltiu $t0, $s0, 25    # if $s0 < 25 then $t0=1 ...
```

Aside: More Branch Instructions

- Can use `slt`, `beq`, `bne`, and the fixed value of 0 in register `$zero` to create other conditions
  - less than

```
blt $s1, $s2, Label
```

```
slt  $at, $s1, $s2      #$at set to 1 if
bne  $at, $zero, Label  #$s1 < $s2
```

  - less than or equal to `ble $s1, $s2, Label`
  - greater than `bgt $s1, $s2, Label`
  - great than or equal to `bge $s1, $s2, Label`

- Such branches are included in the instruction set as pseudo instructions - recognized (and expanded) by the assembler
  - Its why the assembler needs a reserved register (`$at`)

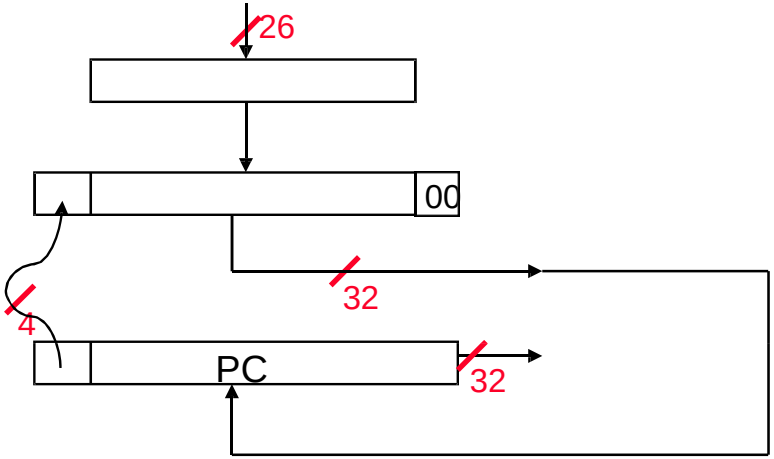
Other Control Flow Instructions

- MIPS also has an unconditional branch instruction or jump instruction:

```
j   label        #go to label
```

- Instruction Format (J Format):

from the low order 26 bits of the jump instruction

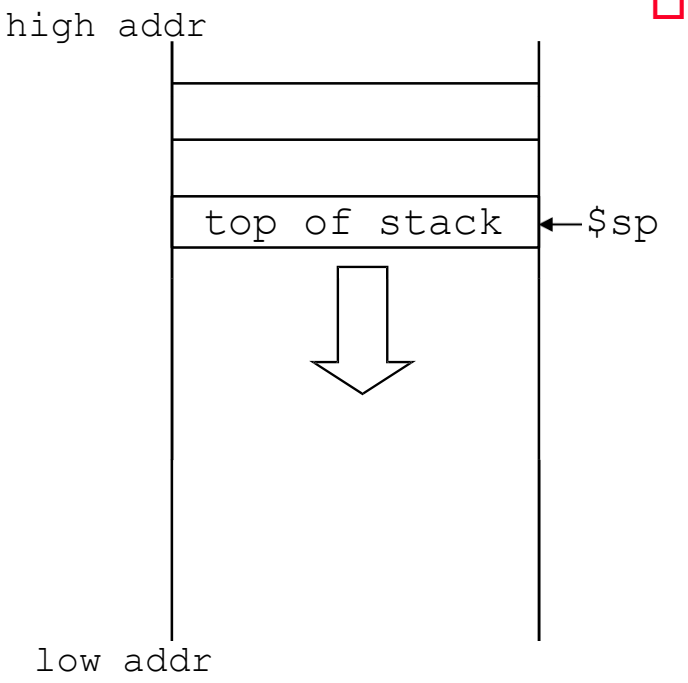


Six Steps in Execution of a Procecure

1. Main routine (caller) places parameters in a place where the procedure (callee) can access them
   - `$a0` - `$a3`: four argument registers
2. Caller transfers control to the callee
3. Callee acquires the storage resources needed
4. Callee performs the desired task
5. Callee places the result value in a place where the caller can access it
   - `$v0` - `$v1`: two value registers for result values
6. Callee returns control to the caller
   - `$ra`: one return address register to return to the point of origin

Aside: SpillingRegisters

- What if the callee needs to use more registers than allocated to argument and return values?
  - callee uses a stack – a last-in-first-out queue

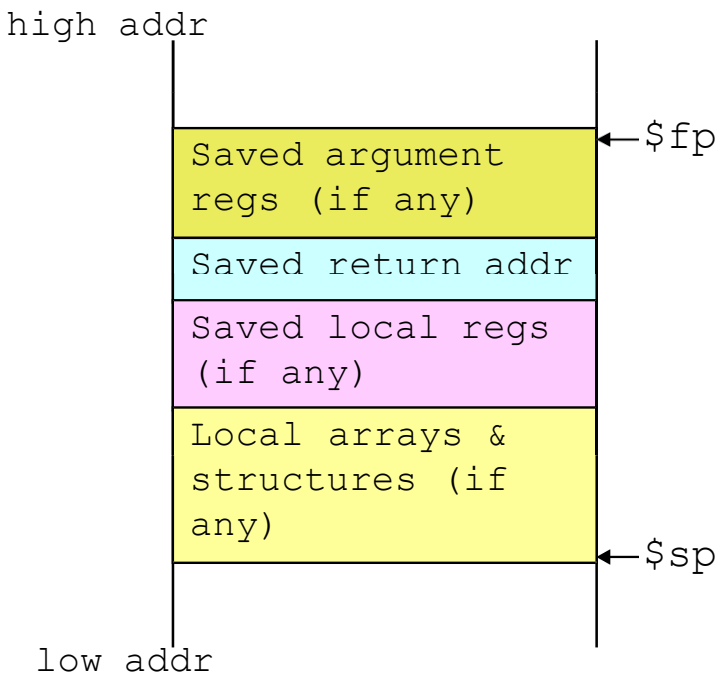


- One of the general registers, `$sp` (`$29`), is used to address the stack (which "grows" from high address to low address)
  - add data onto the stack – push

    `$sp` = `$sp` – 4
    data on stack at new $sp
  - remove data from the stack – pop

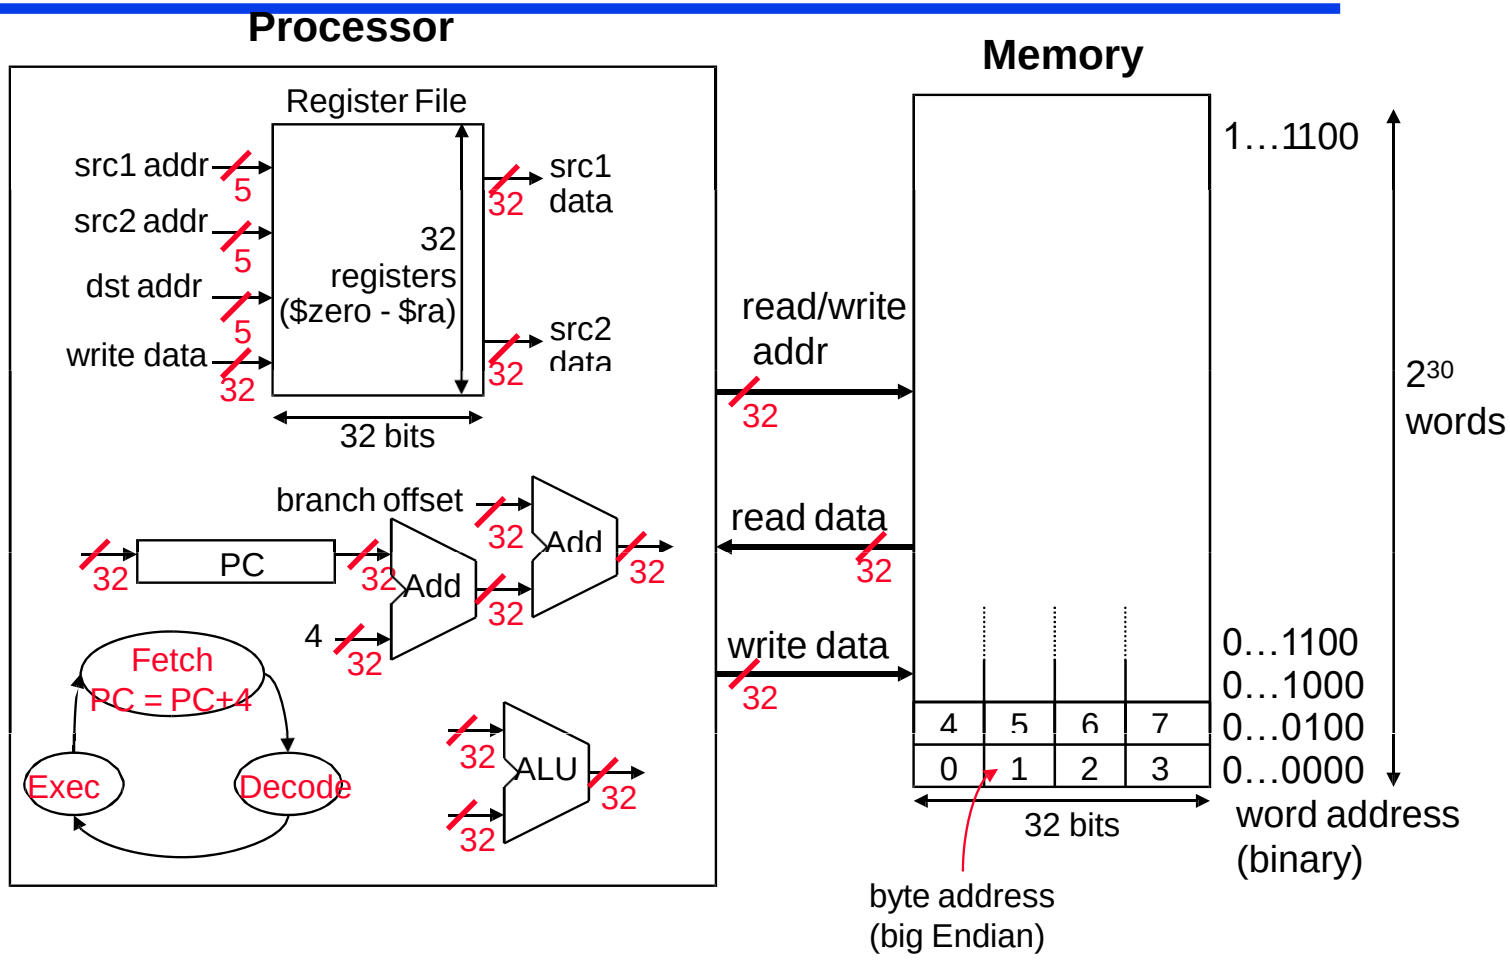
    data from stack at $sp
    `$sp` = `$sp` + 4

Aside: Allocating Space on the stack



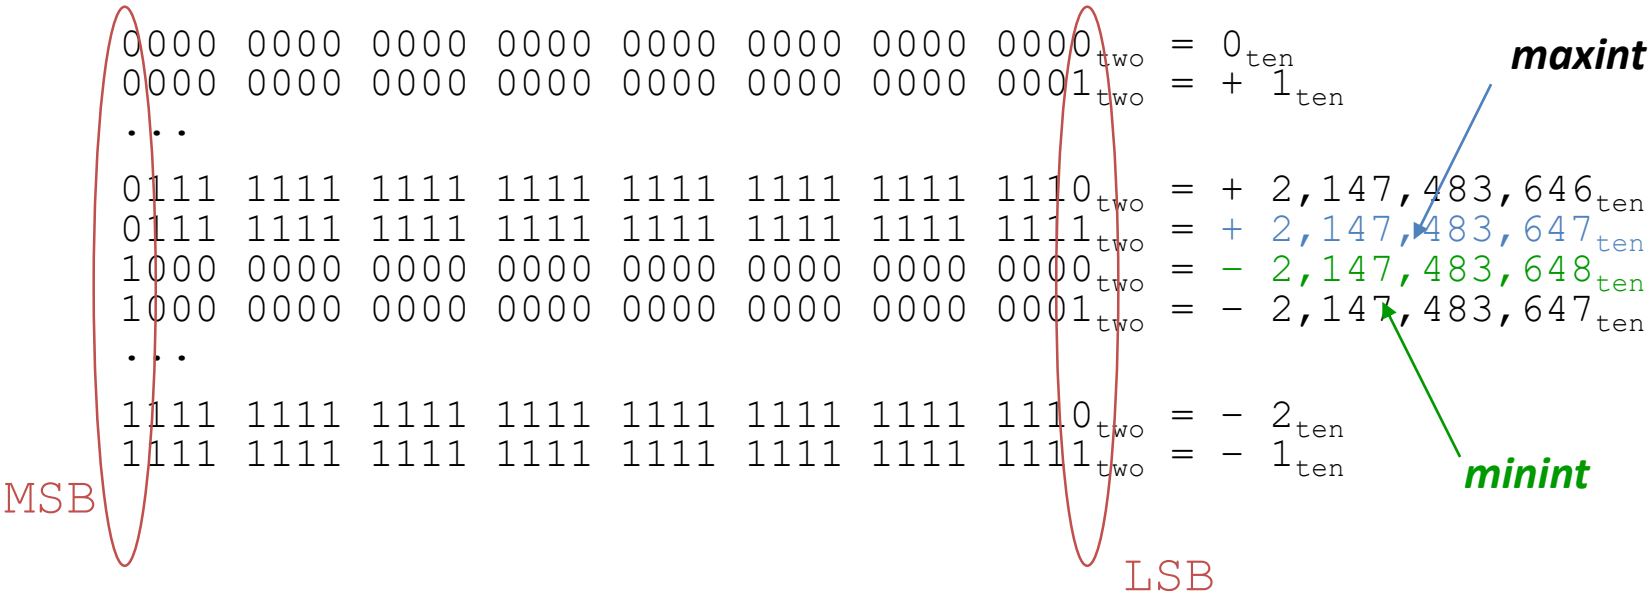
- The segment of the stack containing a procedure's saved registers and local variables is its procedure frame (aka activation record)
  - The frame pointer (`$fp`) points to the first word of the frame of a procedure – providing a stable "base" register for the procedure
    - `$fp` is initialized using `$sp` on a call and `$sp` is restored using `$fp` on a return

MIPS Organization So Far



Number Representations

32-bit signed numbers (2's complement):



- Converting <32-bit values into 32-bit values
  - copy the most significant bit (the sign bit) into the "empty" bits

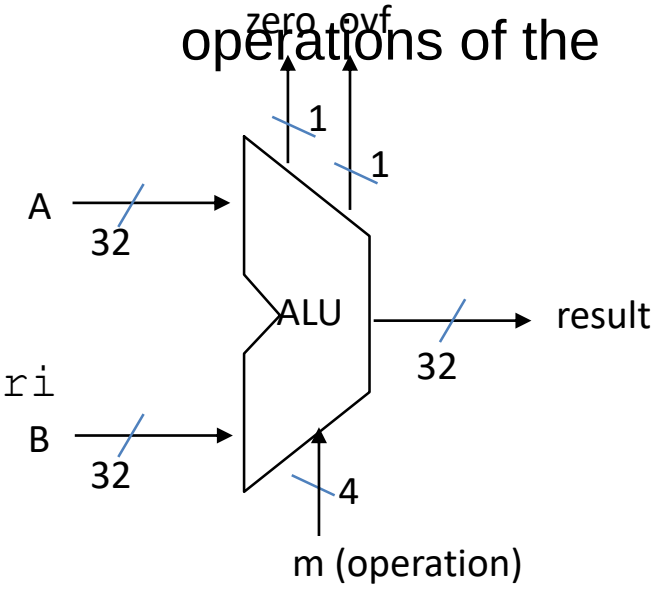
```
0010   -> 0000 0010
1010   -> 1111 1010
```

  - sign extend versus zero extend (`lb` vs. `lbu`)

MIPS Arithmetic Logic Unit (ALU)

Must support the Arithmetic/Logic operations of the ISA

```
add, addi, addiu, addu
sub, subu
mult, multu, div, divu
sqrt
and, andi, nor, or, ori, xor, xori
beq, bne, slt, slti, sltiu, sltu
```



- With special handling for
  - sign extend – `addi, addiu, slti, sltiu`
  - zero extend – `andi, ori, xori`
  - overflow detection – `add, addi, sub`

ARM & MIPS Similarities

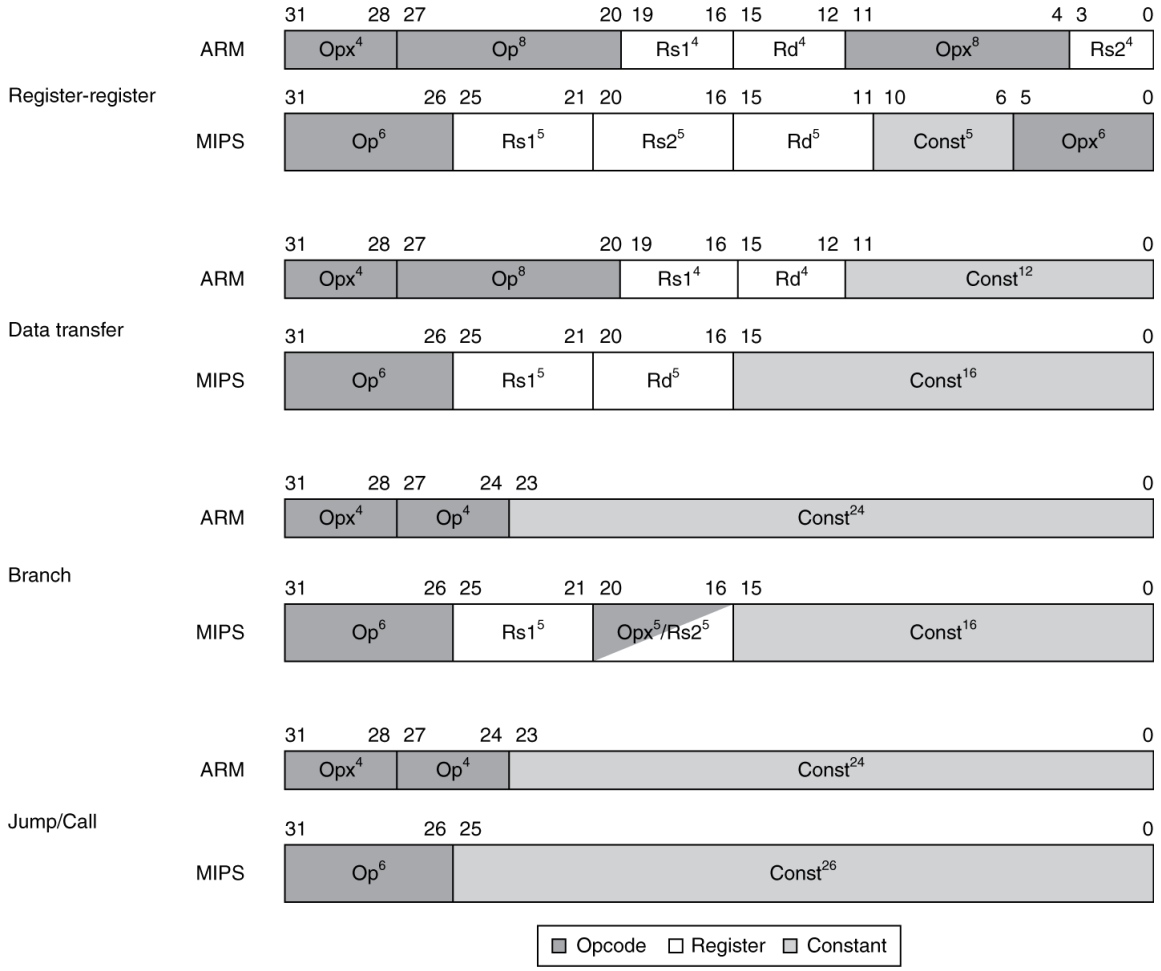
- ARM: the most popular embedded core
- Similar basic set of instructions to MIPS

	ARM	MIPS
Date announced	1985	1985
Instruction size	32 bits	32 bits
Address space	32-bit flat	32-bit flat
Data alignment	Aligned	Aligned
Data addressing modes	9	3
Registers	15 × 32-bit	31 × 32-bit
Input/output	Memory mapped	Memory mapped

Compare and Branch in ARM

- Uses condition codes for result of an arithmetic/logical instruction
  - Negative, zero, carry, overflow
  - Compare instructions to set condition codes without keeping the result
- Each instruction can be conditional
  - Top 4 bits of instruction word: condition value
  - Can avoid branches over single instructions

Instruction Encoding



ARM v8 Instructions

- In moving to 64-bit, ARM did a complete overhaul
- ARM v8 resembles MIPS
  - Changes from v7:
    - No conditional execution field
    - Immediate field is 12-bit constant
    - Dropped load/store multiple
    - PC is no longer a GPR
    - GPR set expanded to 32
    - Addressing modes work for all word sizes
    - Divide instruction
    - Branch if equal/branch if not equal instructions

Fallacies

- Powerful instruction ⇒ higher performance
  - Fewer instructions required
  - But complex instructions are hard to implement
    - May slow down all instructions, including simple ones
  - Compilers are good at making fast code from simple instructions
- Use assembly code for high performance
  - But modern compilers are better at dealing with modern processors
  - More lines of code ⇒ more errors and less productivity

Concluding Remarks

- Measure MIPS instruction executions in benchmark programs
  - Consider making the common case fast
  - Consider compromises

Instruction class	MIPS examples	SPEC2006 Int	SPEC2006 FP
Arithmetic	`add, sub, addi`	16%	48%
Data transfer	`lw, sw, lb, lbu, lh, lhu, sb, lui`	35%	36%
Logical	`and, or, nor, andi, ori, sll, srl`	12%	4%
Cond. Branch	`beq, bne, slt, slti, sltiu`	34%	8%
Jump	`j, jr, jal`	2%	0%

Arithmetic for Multimedia

- Graphics and media processing operates on vectors of 8-bit and 16-bit data
  - Use 64-bit adder, with partitioned carry chain
    - Operate on 8×8-bit, 4×16-bit, or 2×32-bit vectors
  - SIMD (single-instruction, multiple-data)
- Saturating operations
  - On overflow, result is largest representable value
    - c.f. 2s-complement modulo arithmetic
  - E.g., clipping in audio, saturation in video
