University at Buffalo

Banking Example (Once Again)

- Banking transaction for a customer (e.g., at ATM or browser)
  - Transfer $100 from saving to checking account
  - Transfer $200 from money-market to checking account
  - Withdraw $400 from checking account
- Transaction
  1. savings.deduct(100)
  2. checking.add(100)
  3. mnymkt.deduct(200)
  4. checking.add(200)
  5. checking.deduct(400)
  6. dispense(400)

Transaction

- Abstraction for grouping multiple operations into one
- A transaction is indivisible (atomic) from the point of view of other transactions
  - No access to intermediate results/states
  - Free from interference by other operations
- Primitives
  - begin(): begins a transaction
  - commit(): tries completing the transaction
  - abort(): aborts the transaction & rolls back to the previous state (as if nothing happened)
- Why abort()?  
  - A failure happens in the middle of execution.
  - A transaction is part of a bigger transaction (i.e., it’s a sub-transaction), and the bigger transaction needs abort.
  - Etc.

Properties of Transactions: ACID

- Atomicity: All or nothing
- Consistency: if the server starts in a consistent state, the transaction ends with the server in a consistent state.
- Isolation: Each transaction must be performed without interference from other transactions, i.e., the non-final effects of a transaction must not be visible to other transactions.
- Durability: After a transaction has completed successfully, all its effects are saved in permanent storage.

This Week

- Question: How to support transactions?
  - Multiple transactions share data.
- What would be your first strategy (hint: locks)?
  - One transaction at a time with one big lock, i.e., complete serialization
- Two issues
  - Performance
  - Abort

Performance?

- Process 1
  - lock(mutex);
  - savings.deduct(100);
  - checking.add(100);
  - mnymkt.deduct(200);
  - checking.add(200);
  - checking.deduct(400);
  - dispense(400);
  - unlock(mutex);

- Process 2
  - lock(mutex);
  - savings.deduct(200);
  - checking.add(200);
  - unlock(mutex);
Abort?

- An abort at these points means the customer loses money; we need to restore old state.
- An abort at these points does not cause lost money, but old steps cannot be repeated.

This Week

- Question: How to support transactions?
  - Multiple transactions share data.
- What would be your first strategy (hint: locks)?
  - Complete serialization
    - One transaction at a time with one big lock
  - Two issues: Performance and abort
- First, let’s see how we can improve performance.
  - By executing multiple transactions concurrently

What Can Go Wrong?

- Transaction T1
  - balance = b.getBalance()
  - b.setBalance = (balance*1.1)
  - a.withdraw(balance*0.1)
- Transaction T2
  - balance = b.getBalance()
  - b.setBalance = (balance*1.1)
  - c.withdraw(balance*0.1)

  - T1/T2’s update on the shared object, “b”, is lost.

Lost Update Problem

- One transaction causes loss of info. for another: consider three account objects

  - Transaction T1
    - balance = b.getBalance()
    - b.setBalance = (balance*1.1)
    - a.withdraw(balance*0.1)
  - Transaction T2
    - balance = b.getBalance()
    - b.setBalance = (balance*1.1)
    - c.withdraw(balance*0.1)

  - T1/T2’s update on the shared object, “b”, is lost.

Inconsistent Retrieval Problem

- Partial, incomplete results of one transaction are retrieved by another transaction.

  - Transaction T1
    - a.withdraw(100)
    - total = a.getBalance()
    - total = total + b.getBalance

  - Transaction T2
    - b.deposit(100)
    - total = total + c.getBalance

  - T1’s partial result is used by T2, giving the wrong result.
What This Means

- Question: How to support transactions (with locks)?
  - Multiple transactions share data.
- Complete serialization is correct, but performance and abort are two issues.
- Executing transactions concurrently for performance
  - Problem: Not all current executions produce a correct outcome

What is “Correct”?

- How would you define correctness?
- For example, two independent transactions made by me and my wife on our three accounts.
- What do we care about at the end of the day?
  - Correct final balance for each account

Concurrent Control: Providing “Correct” Interleaving

- An interleaving of the operations of 2 or more transactions is said to be serially equivalent if the combined effect is the same as if these transactions had been performed sequentially in some order.

Providing Serial Equivalence

- What operations are we considering?
  - Read/write
- What operations matter for correctness?
  - When write is involved

Conflicting Operations

- Two operations are said to be in conflict if their combined effect depends on the order in which they are executed, e.g., read-write, write-read, write-write (all on same variables). NOT read-read, not on different variables.
Conditions for Correct Interleaving

- What should we need to do to guarantee serial equivalence with conflicting operations?
- Case 1
  - T1.1 -> T1.2 -> T2.1 -> T2.2 -> T1.3 -> T2.3
- Case 2
  - T1.1 -> T2.1 -> T2.2 -> T1.2 -> T1.3 -> T2.3
- Which one’s correct and why?

Conflicting Operations

- Insight for serial equivalence
  - Outcomes of write operations in one transaction to all shared objects should be either consistently visible to the other transaction or the other way round.
  - The effect of an operation refers to
    - The value of an object set by a write operation
    - The result returned by a read operation.
- Two transactions are serially equivalent if and only if all pairs of conflicting operations (pair containing one operation from each transaction) are executed in the same order (transaction order) for all objects (data) they both access.

Example of Conflicting Operations

- An interleaving of the operations of 2 or more transactions is said to be serially equivalent if the combined effect is the same as if these transactions had been performed sequentially (in some order).

Another Example

- Serially-equivalent interleaving of operations

Inconsistent Retrievals Problem

- Both withdraw and deposit contain a write operation

Serially-Equivalent Ordering

- Outcomes for serial equivalence
Summary

• Transactions need to provide ACID
• Serial equivalence defines correctness of executing concurrent transactions
• It is handled by ordering conflicting operations
