Byzantine Fault Tolerance

- Fault categories
 - Benign: failures we've been talking about
 - Byzantine: arbitrary failures
- Benign
 - Fail-stop & crash: process halted
 - Omission: msg loss, send-omission, receive-omission
 - All entities still follow the protocol
- Byzantine
 - A broader category than benign failures
 - Process or channel exhibits arbitrary behavior.
 - May deviate from the protocol
 - Processes can crash, messages can be lost, etc.
 - Can be malicious (attacks, software bugs, etc.)

CSE 486/586

2

Byzantine Fault Tolerance

- Can we achieve **consensus** when there are f **faulty** nodes?
 - But we're not bypassing the impossibility result (e.g., we still need to mask benign failures.)
- Result: with f **faulty nodes**, we need $3f + 1$ nodes to tolerate their Byzantine behavior.
 - Fundamental limitation
 - Today's goal is to understand this limitation.
- How about Paxos (that tolerates benign failures)?
 - With f faulty nodes, we need $2f + 1$ (i.e., we need a correct majority.)
 - Having f faulty nodes means that as long as $f + 1$ nodes are reachable, Paxos can guarantee an agreement.
 - This is the known lower bound for consensus with non-Byzantine failures.

3

"Byzantine"

- Leslie Lamport (again!) defined the problem & presented the result.
- *"I have long felt that, because it was posed as a cute problem about philosophers seated around a table, Dijkstra's dining philosopher's problem received much more attention than it deserves."*
- *"At the time, Albania was a completely closed society, and I felt it unlikely that there would be any Albanians around to object, so the original title of this paper was The Albanian Generals Problem."*
- *"...The obviously more appropriate Byzantine generals then occurred to me."*

4

Introducing the Byzantine Generals

- Imagine several divisions of the Byzantine army camped outside of a city
- Each division has a general.
- The generals can only communicate by a messenger.

CSE 486/586

5

Introducing the Byzantine Generals

- They must decide on a common plan of action.
 - What is this problem?
- But, **some of the generals can be traitors.**
- Quick example to demonstrate the problem:
 - One commander and two lieutenants
 - With one traitor, can non-traitors decide on a common plan?

CSE 486/586

6

Understanding the Problem

- Setup: One commander & two lieutenants
- Protocol
 - Commander sends a command (either attack or retreat) to the two lieutenants.
 - Each lieutenant forwards the command to the other lieutenant in case messages get lost.
- Goal
 - Deciding on the same plan of action (either attack or retreat)

CSE 486/586

7

Understanding the Problem

- Can the lieutenants determine that the commander is the traitor?

CSE 486/586

8

Understanding the Problem

- For lieutenant 1, this looks exactly the same as the previous scenario.

CSE 486/586

9

Understanding the Problem

- In the example, one traitor ($f = 1$) makes it impossible to reach consensus with three generals ($2f + 1$ generals).
- Or more generally, when f nodes can behave arbitrarily (Byzantine), $2f + 1$ nodes are not enough to tolerate it.
 - This is unlike Paxos (reaching consensus while tolerating non-Byzantine failures).

CSE 486/586 Administrivia

- PA4 deadline: 5/10
- Final exam: 5/17 @ 11:45 am – 2:45 pm in Knox 109
 - Includes everything
 - True/false questions & multi-choice questions
 - Cheat sheet allowed (1-page, letter-sized, front-and-back)
 - No restroom use
- Survey & course evaluation
 - Survey: <https://forms.gle/eq1wHN2G8S6GVz3e9>
 - Course evaluation: <https://www.smartevals.com/login.aspx?s=buffalo>
- Incentive when both have 80% or more participation
 - Currently about 50% for both
- No recitation this week; replaced with office hours

CSE 486/586

11

More Practical Setting

- Replicated Web servers
 - Multiple servers running the same state machine.
 - For example, a client asks a question and each server replies with an answer (yes/no).
 - The client determines what the correct answer is based on the replies.

CSE 486/586

12

More Practical Setting

- f Byzantine failures
 - At any point of time, there can be up to f failures.
- Ambiguity (many possibilities) of a failure
 - A crashed process, a message loss, malicious behavior (e.g., a lie), etc., **but a client cannot tell which one it is.**
 - But in total, the maximum # of failures is bounded by f .

BFT Question

- Given f , how many nodes do we need to tolerate f Byzantine failures?
 - f failures can be any mix of malicious servers, crashed servers, message losses, etc.
 - Malicious servers can do anything, e.g., they can lie (if yes, say no, if no, say yes).

Intuition for the Result

- Let's say we have n servers, and maximum f Byzantine failures.
- What is the minimum # of replies that you are **always** guaranteed to get?
 - $n - f$
 - Why? f maximum failures can all be crashed processes

Intuition for the Result

- The problem is that we're unsure what those f failures are. So we have to think about **many possibilities.**
- Upon receiving $n - f$ replies (guaranteed), are we really sure that f replies will never come?
 - No, those f replies could be from **slow but correct** processes.

Intuition for the Result

- Let's put it together. We have two possibilities.
- With $n - f$ replies, there is no guarantee that f replies will come, i.e., **the client needs to determine what the correct answer is when it has $n - f$ replies.**
- At the same time, there's no way to tell if those f replies are actual failures or from **slow processes.**

Intuition for the Result

- If those f replies are from **slow processes**, then they are still correct. They don't count towards f failures.
- This means that **out of $n - f$ replies, there can still be f replies from f Byzantine nodes.**
- This leaves us with f processes that can be malicious that have already replied.

Intuition for the Result

- Then the question is: out of $n - f$ replies and possible f malicious replies contained among them, how can we make sure that we can always determine the correct answer?
 - If we make sure that $n - f$ replies always contain more replies from honest nodes than Byzantine nodes, we're safe.

Intuition for the Result

- Answer: we make sure that we always get $f + 1$ replies from honest nodes, one more than the number of potentially-malicious nodes, f .
 - We set $n = 3f + 1$
 - When we get $n - f$ replies, it is $2f + 1$ replies. At least $f + 1$ replies from honest nodes, and at most f replies from malicious nodes.

Write/Read Example

- One client writes to X .
- A malicious node omits it.
- Another client reads X .
- It can still get the latest write.

Summary

- Byzantine generals problem
 - They must decide on a common plan of action.
 - But, some of the generals can be traitors.
- Requirements
 - All loyal generals decide upon the same plan of action (e.g., attack or retreat).
 - A small number of traitors cannot cause the loyal generals to adopt a bad plan.
- Impossibility result
 - In general, with less than $3f + 1$ nodes, we cannot tolerate f faulty nodes.
