CSE 486/586

### Last Time

- Ordering of events
  - Many applications need it, e.g., collaborative editing, distributed storage, etc.
- Logical time
  - Lamport clock: single counter
  - Vector clock: one counter per process
  - Happens-before relation shows **causality of events**

CSE 486/586

2

### Today's Topic

- Global snapshots
- An "application" of logical time
- Today's topic will deepen your understanding about causality and the abstract view of distributed systems.

CSE 486/586

3

### Today's Question

- Example question: who has the most friends on Facebook?
- Challenges to answering this question?
  - It changes!

- What do we need?
  - A **snapshot** of the social network graph at a particular time

CSE 486/586

4

### Today's Question

- Distributed debugging

- How do you debug this?
  - Log in to one machine and see what happens
  - Collect logs and see what happens
  - Taking a **global snapshot!**

CSE 486/586

5

### What is a Snapshot?

- Single process snapshot
  - Just a snapshot of the local state, e.g., memory dump, stack trace, etc.
  - For the sake of this lecture, let's say a log of events.
  - When we capture a snapshot, we want to be able to **trace the causality** (e.g., important for debugging).

- Let's say we're logging all events.
  - The above snapshot (a dump of log messages) will include e<sub>1</sub><sup>0</sup> and e<sub>1</sub><sup>1</sup>. This allows us to trace the causality of events.
  - How to do this for a multiple processes?

CSE 486/586

6

## Ideal: Instantaneous Snapshot

- Process snapshots and network messages at time  $t$

- The most general multi-process snapshot that can explain all causality
  - Causality across processes
  - Messages caused by send events
- But we can't quite do it due to imperfect clock sync.
- We do it thru logical snapshots.

CSE 486/586

7

## How to Do It? Definitions

- For a process  $P_i$ , where events  $e_i^0, e_i^1, \dots$  occur,
  - $history(P_i) = h_i = \langle e_i^0, e_i^1, \dots \rangle$
  - $prefix\ history(P_i^k) = h_i^k = \langle e_i^0, e_i^1, \dots, e_i^k \rangle$
  - $S^k$ :  $P_i$ 's state immediately after  $k^{th}$  event
- For a set of processes  $P_1, \dots, P_i, \dots$ :
  - Global history:**  $H = \cup (h_i)$
  - Global state:**  $S = \cup (S_i^k)$
  - A cut:**  $C \subseteq H = h_1^{c_1} \cup h_2^{c_2} \cup \dots \cup h_n^{c_n}$
  - The frontier of  $C$ :**  $= \{e_i^{c_i}, i = 1, 2, \dots, n\}$

CSE 486/586

8

## Consistent States

- A cut  $C$  is **consistent** if and only if
  - $\forall e \in C (if\ f \rightarrow e\ then\ f \in C)$
- A global state  $S$  is **consistent** if and only if
  - it corresponds to a consistent cut

CSE 486/586

9

## CSE 486/586 Administrivia

- PA2-A deadline: This Friday
- PA1: some hiccups, getting delayed
- Please come and ask questions during office hours.

CSE 486/586

10

## The Snapshot Algorithm: Assumptions

- There is a **communication channel** between each pair of processes (@each process: N-1 in and N-1 out)
- Communication channels are unidirectional and **FIFO-ordered (important point)**
- No failure, all messages arrive intact, exactly once**
- Any process may initiate the snapshot
- Snapshot does not interfere with normal execution
- Each process is able to record its state and the state of its incoming channels (no central collection)

CSE 486/586

11

## Reminder: Clock-Sync'd Snapshot

- Instantaneous snapshot
  - Process snapshots and network messages at time  $t$
  - We can't quite do it due to imperfect clock sync.

CSE 486/586

12

## Chandy and Lamport's Snapshot: Basic Idea

- Goal: taking a **consistent** (not instantaneous) global snapshot
- Any process can initiate a snapshot-taking process by taking a local snapshot and sending a message called a **marker**.
- Upon receiving a marker, a process takes a **local** snapshot of its own.
- How do we capture network messages?
  - Insight: messages in flight will eventually arrive.

CSE 486/586

13

## Chandy and Lamport's Snapshot: Basic Idea

- Each process that has taken a snapshot also starts recording **incoming messages**
  - Since those messages were in the network when the snapshot was being taken.
  - If every process does this, we will capture all messages in flight, recording messages destined to each process.
  - Note: every process needs to do this for **every other process**.
- Tricky part: the algorithm has a mechanism to **stop recording incoming messages** at some point.

CSE 486/586

14

## Chandy and Lamport's Snapshot: Basic Idea

- Reminder: which messages do we want to record?
  - Messages that were in the network at the time of taking a snapshot
- How do we record just those messages?
  - Insight: we can mark the **end of relevant messages**.
- After taking a local snapshot, each process sends a message saying that it's done sending all messages relevant to the snapshot.
  - In fact, we don't need a different message type, we use the same marker message.

CSE 486/586

15

## Chandy and Lamport's Snapshot

- **Marker broadcast & recording**
  - The initiator **broadcasts a "marker" message** to everyone else
  - If a process receives a marker **for the first time**, it takes a local snapshot, starts **recording all incoming messages**, and **broadcasts a marker again** to everyone else.
  - A process stops recording for each channel, when it receives a marker for that channel.

CSE 486/586

16

## The Snapshot Algorithm

1. Marker **sending rule** for initiator process  $P_0$ 
  - After  $P_0$  has recorded its own state
    - for each outgoing channel  $C$ , send a marker message on  $C$
2. Marker **receiving rule** for a process  $P_k$  **on receipt of a marker over channel  $C$** 
  - if  $P_k$  has not yet recorded its own state
    - record  $P_k$ 's own state
    - record the state of  $C$  as "empty"
    - for each outgoing channel  $C$ , send a marker on  $C$
    - turn on recording of messages over other incoming channels
  - else
    - record the state of  $C$  as all the messages received over  $C$  since  $P_k$  saved its own state; stop recording state of  $C$

CSE 486/586

17

## Exercise

- 1-  $P_1$  initiates snapshot: records its state ( $S_1$ ); sends Markers to  $P_2$  &  $P_3$ ; turns on recording for channels  $C_{21}$  and  $C_{31}$
- 2-  $P_2$  receives Marker over  $C_{12}$ , records its state ( $S_2$ ), sets state( $C_{12}$ ) = {} sends Marker to  $P_1$  &  $P_3$ ; turns on recording for channel  $C_{32}$
- 3-  $P_1$  receives Marker over  $C_{21}$ , sets state( $C_{21}$ ) = {a}
- 4-  $P_3$  receives Marker over  $C_{13}$ , records its state ( $S_3$ ), sets state( $C_{13}$ ) = {} sends Marker to  $P_1$  &  $P_2$ ; turns on recording for channel  $C_{23}$
- 5-  $P_2$  receives Marker over  $C_{32}$ , sets state( $C_{32}$ ) = {b}
- 6-  $P_3$  receives Marker over  $C_{23}$ , sets state( $C_{23}$ ) = {}
- 7-  $P_1$  receives Marker over  $C_{31}$ , sets state( $C_{31}$ ) = {}

CSE 486/586

18

## One Provable Property

- The snapshot algorithm gives a **consistent cut**
- Meaning,
  - Suppose  $e_i$  is an event in  $P_i$ , and  $e_j$  is an event in  $P_j$
  - If  $e_i \rightarrow e_j$ , and  $e_j$  is in the cut, then  $e_i$  is also in the cut.
- Proof sketch: proof by contradiction
  - Suppose  **$e_j$  is in the cut, but  $e_i$  is not.**
  - Since  $e_i \rightarrow e_j$  there must be a sequence  $M$  of messages that leads to the relation.
  - Since  $e_i$  is not in the cut (our assumption), a marker should've been sent before  $e_i$ , and also before all of  $M$ .
  - Then  $P_j$  must've recorded a state before  $e_j$ , meaning,  $e_j$  is not in the cut. (Contradiction)

CSE 486/586

19

## Summary

- Global states
  - A union of all process states
  - Consistent global state vs. inconsistent global state
- The "snapshot" algorithm
  - Take a snapshot of the local state
  - Broadcast a "marker" msg to tell other processes to record
  - Start recording all msgs coming in for each channel until receiving a "marker"
  - Outcome: a consistent global state
